出版前言

2011年12月11日是西安交通大学杰出校友钱学森先生的百年诞辰。为缅怀钱学森学长,学习他的科学思想和卓越风范,展示其丰功伟绩和人格魅力,西安交通大学举办了“纪念钱学森诞辰100周年”系列活动:作为制片方之一,参与西部电影集团摄制传记故事片《钱学森》;与中央电视台合作,出品纪录片《实验班的故事——沿着钱学森走过的路》;扩建钱学森生平业绩展馆,向校内外开放;举办钱学森科学与教育思想研讨会;出版发行《钱学森力学手稿》、《钱学森年谱(初编)》、《钱学森第六次产业革命思想探微丛书》等。

钱学森先生在美国深造和工作期间留下大量珍贵手稿,这些手稿真实展示了钱学森先生博大精深的学识、开拓求实的精神和严谨奋进的作风,是钱老勇攀科学高峰和严谨治学的集中体现。这里,我们将部分原稿整理汇集成册,出版《钱学森力学手稿》,作为钱老百年诞辰的献礼。

《钱学森力学手稿》共10卷,包含两部分内容。第一部分是草稿,包括扁壳、球壳和圆柱壳屈曲分析的公式推导和数值演算。在研究圆柱壳轴压屈曲问题时,为了求得圆柱壳体的临界压力,在有关的五百多页草稿中,对多达二十多种可能的屈曲模

态逐一进行公式推演和数值计算,最终才找到满意的并在论文中采用的屈曲模态。仔细观察草稿中的数据列表,每个数字有效位数都长达八位,在手摇机械式计算机作为主要计算工具的年代,这串串数字凝聚着多少现今难以想象的艰辛劳动。

第二部分是手稿,以航空航天工程为核心,涵盖空气动力学、固体力学、火箭技术、工程控制论和物理力学等领域的部分学术论文手稿、打印稿和讲义。

《钱学森力学手稿》是在西安交通大学学校领导的大力支持下,由西安交通大学航天航空学院沈亚鹏教授整理完成。图书出版过程中得到了西安交通大学党委宣传部、校友关系发展部、图书馆、航天航空学院等的积极协助,在此深表感谢。

Wind-Tunnel Testing Problems in Supercritical Aerodynamics

Hans-Joachim Thiele

Guggenheim Aeronautical Laboratory
Massachusetts Institute of Technology

Wind-tunnels are, perhaps, the most useful tool in aerodynamic investigations and certainly have contributed much in the modern development of fluid mechanics. It is ^{thus} natural, when one turns to the new field of aerodynamics, the aerodynamics of rarefied gases or supercritical aerodynamics, that one should think of using the wind-tunnel again. Only here ~~the old faithful tool~~ ^{it} has to be adapted to entirely new circumstances and many new problems, both in its design and in its operation, appear. It is the purpose of this paper to discuss some of these problems, to gain an orientation in the new field of experimentation.

1. Tunnel Design

To test models in the wind tunnel at its test section, it is of primary importance to obtain a uniform stream at the desired temperature, pressure and velocity. For subsonic wind tunnels with ordinary pressures, this can be achieved without much difficulty. For supersonic wind tunnels at ordinary pressures, the expansion part of the tunnel, ~~or the nozzle~~, before the test section, is first designed to obtain a uniform stream at its exit without considering the ^{exit of the} velocity of air. Then the boundary layer along the wall of the nozzle is calculated with the pressure gradient thus determined. Finally the thickness of the boundary layer, or rather the ^{needed} ~~enlarged~~ space for the boundary layer flow at lower velocity is provided by making the nozzle larger than the dimensional first determined by the calculated amount. (Ref. 1) This design procedure is found to give satisfactory nozzles for supersonic wind tunnels.

There is a problem when one tries to use the same design of studies to the entire body, because a substantial error is introduced by neglecting the difficulty of extremely small effect. In this case, the boundary layer will be so thick as to obscure the main features of the wave passage. To do without this effect let us consider that the length of the test section is L and the width of the test section is b . Then the boundary layer is based upon the conditions in the test section as $Re = \frac{U L}{\nu}$, where

U is the velocity in the test section. If we make a rough estimate, we take the thickness of the boundary layer to be 20% of the length of the test section, and equal to the value obtained by the following formula for a flat plate at the end of the test section, then

$$\delta = 3.65 L \frac{1}{\sqrt{Re}} \quad (1)$$

Now if the boundary layer actually occupies half of the test section, then

$$\frac{\delta}{L} = 0.5 = 3.65 \frac{1}{\sqrt{Re}}$$

On the other hand, the ratio of the area of the boundary layer to the secondary layer thickness δ is given by eq. 21 to be equal to

$$\frac{A}{\delta} = \frac{1.05 \sqrt{Re}}{3.65} = \frac{11}{3.65}$$

where γ is the ratio of characteristic length l to the distance x from the test section. By combining eq. 1 and eq. 2, we have

$$\frac{1}{\delta} - \frac{1}{L} = 0.5 \sqrt{Re} \quad (2)$$

This relation is shown in Fig. 1. Thus for a fixed number of Re at the 2, and $L/\delta = 2$, the boundary layer will be 1/2 the total length.

the test section as the mean free path is equal to the distance between layers thickness is 2δ of the test section. This means that the velocity at the surface is zero at the distance δ makes the velocity profile of shear flow in a test section approximately

The mean flow can be approximated by calculating the velocity of the fluid at the inlet and outlet sections and the shock loss in the section. Consider the difference between the static pressure of air in the same cross section as in the test section, the pressure loss due to friction, Δp_1 is

$$\Delta p_1 = \frac{2\mu u_m L}{b^3}$$

$$= \frac{2\mu}{b^3} \cdot \frac{1}{2} \pi b^2 L \cdot \frac{4}{\pi} \frac{Q}{b^2}$$

Taking μ as the dynamic viscosity of air at 20°C and Q as the flow rate

$$\Delta p_1 = 2\mu \frac{Q}{b^3} \frac{L}{\pi}$$

In the shock loss in the test section is not a loss of energy as the shock with no recovery after the shock. Then if p is the pressure in the test section the pressure loss due to the shock is

$$\Delta p_2 = \left[1 + \frac{\gamma-1}{2} M^2 \right]^{-\frac{\gamma}{\gamma-1}} - 1 \frac{2\gamma}{\gamma+1} M^2 - \frac{\gamma-1}{\gamma+1} \frac{1}{2} \gamma$$

If γ is constant and M is the Mach number of the flow in the test section

$$\frac{\Delta p_2}{\rho U^2} = \frac{2\gamma M^2 (\frac{1}{b})}{1 + \frac{\gamma-1}{2} M^2} \frac{1.324}{\sqrt{Re}} \quad (2)$$

Introducing the free path ratio given by (13), we have

$$\Delta p_2 / \Delta p_1 = 16/81 \left(1 + \frac{1}{2} \frac{1}{\lambda} + \frac{1}{8} \frac{1}{\lambda^2} + \dots \right) \approx 1.27 \frac{1}{\lambda} \quad (14)$$

which is plotted in Fig. 2. Therefore if Mach number M is 2 and the ratio of freestream flow to shock flow is 0.628, therefore the freestream flow and the shock flow is of the same order of magnitude.

Design of the nozzle (and test section for a supersonic flow) is complicated, it is no longer possible to approximate the compressibility

effects as in the case of subsonic flow. Therefore to actually design such a nozzle to obtain the nearest approximation to the ideal uniform flow, it will be necessary to use the exact Navier-Stokes

Of course, it may be argued that for supersonic flows, the Navier-Stokes equations for no more exact and additional corrections must be added (Ref. 4). However, recent investigations (R. Schanberg (Ref. 3)) have shown that these additional corrections essentially alter the flow pattern. Hence for a first approximation, just like the inviscid isentropic flow as a first approximation for ordinary supersonic nozzles, we can use the Navier-Stokes equations. The simplest case to be considered is certainly the axially symmetric nozzles. If x is the axial coordinate in the nozzle, r the coordinate in the radial direction and u, v, w the corresponding velocity components, the

$$\frac{1}{r} \frac{\partial}{\partial r} (r u) + \frac{\partial u}{\partial x} = 0 \quad (15)$$

$$\rho \frac{dv_x}{dt} = - \frac{\partial p}{\partial x} - \text{grad}(\tau)_x \quad (A)$$

$$\rho \frac{dv_r}{dt} = - \frac{\partial p}{\partial r} - \text{grad}(\tau)_r$$

$$\left(\frac{D}{Dt} \left(\frac{1}{2} v^2 + \hat{p} T \right) \right) = \Phi - \mu \text{grad}(v_r)_r + \nu \left(\frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial v_r}{\partial r} \right) + \frac{1}{r^2} \frac{\partial}{\partial r} \left(r \frac{\partial T}{\partial r} \right) \right)$$

then $\frac{D}{Dt} = u \frac{\partial}{\partial x} + v \frac{\partial}{\partial r}$
 $\Phi = \text{dissipation function}$
 $\tau = \text{stress tensor}$

(9), (10), (11) ⁽¹²⁾ together with the equation of state $\frac{p}{f} = RT \quad (13)$

the determination of the five unknowns u, v, T, p, τ requires the actual process of making the calculations. The first step is a distance approximation, and it is at this point that the general idea of the method, which is to adapt the functions u, v, T, p, τ to the distance r , becomes clear. The functions are assumed to be of the form of a polynomial in r . Which one of the functions is assumed to be a polynomial is decided by S. A. Schaff (Ref. 12) as the nature of the problem. The functions are assumed to be of the form of a polynomial in r . Which one of the functions is assumed to be a polynomial is decided by S. A. Schaff (Ref. 12) as the nature of the problem. The functions are assumed to be of the form of a polynomial in r . Which one of the functions is assumed to be a polynomial is decided by S. A. Schaff (Ref. 12) as the nature of the problem.

It is to be added by saying a lot for possible
rest etc.

100

The quantities p, ρ, T are not independent of each other. Any two of the three variables p, ρ, T are related by the equation of state and hence only two is necessary for the determination of all three. Thus, for each element, the quantities p, ρ, T are not independent of each other.

The most important factor in the design of a pump is the pressure, one sees a fluid manometer of the air water and mercury. However for the extremely low pressure used in the design of a pump, as when flow of air is in a vacuum, the most used type is the Pirani pump. The Pirani pump is a gas sensitive device which is used to measure the pressure of the gas surrounding it. The temperature is a factor in the choice in the construction of the wire. The wire is heated to a temperature which is related to the pressure and the resistance of the wire is the greater of the pressure is increased. The question of best design of the connecting tube is also a factor and is dealt by S. A. Schuff. (Ref 5)

... ..
... ..

$$a_{\text{eff}} = \sqrt{\frac{E}{\pi \mu}}$$

and the stagnation point is located at

$$r_s = \sqrt{\frac{3A}{4\pi U}} = \frac{\sqrt{3}}{2} R_2$$

The velocity introduced by the source = $h\nu/mc$

$$= \frac{1}{4} \frac{R^2}{r^2}$$

1. calculating the seismic stress from the approximate disturbance

$$u \frac{\partial u}{\partial r} + \frac{1}{r} \frac{\partial p}{\partial r} = + \nu u r^2 \frac{\partial^3}{\partial r^3} \quad (16)$$

Since p_0 is the stagnation pressure and p' the ~~free stream~~^{static} pressure,

$$p_0 - p = \frac{1}{2} \rho u^2 + \mu u R^2 \frac{3}{2} \int_{-\infty}^{\infty} \frac{d\tau}{\tau^2}$$

$$= \frac{1}{2} \rho u^2 - \frac{1}{2} \mu u R^2$$

$$O_r \quad f_0 - f^* \equiv \frac{1}{2} \rho u^2 \left[1 - \frac{8}{3\sqrt{3}} \frac{\nu}{u} \right] \quad (17)$$

in dependence there is based upon the assumption of very high clock
backrest, as to the same free path. There is 'reaped' flows, the

position of the probe must be so arranged as to cause interference with flow in the neighbourhood of the Pitot-tube. This together with the assumption that the probe is small compared with the diameter of the tube, leads to the formula for a probe of radius r at a distance x from the wall:

where q is the rate of generation of atoms, ρ is the total mass density, c is the speed of sound, u is the velocity of the gas stream, θ is the angle of inclination of the probe to the flow direction. If the probe is small compared with the diameter of the tube, and q is small compared with the rate of loss of atoms from the probe, the rate of the reaction per unit area of the probe is given by $q/4\pi r^2$. Hence we have for the rate of the reaction per unit area of the probe:

where θ is the angle of inclination of the probe to the flow direction. (Eq. 2) We have thus a simple physical situation. If θ is the inclination of the probe to the flow direction, u is the velocity of the gas stream, c is the speed of sound, ρ is the density of the gas, E_i is the incident energy per unit area, and E_r is the reflected energy per unit area, then we have as

$$E_{i_{hr}} = \rho \frac{c}{2\sqrt{\pi}} \int_0^\pi e^{-\frac{u^2}{c^2} \sin^2 \theta} (c^2 + \frac{1}{2} u^2)$$

$$+ \frac{1}{2} (c^2 + \frac{1}{2} u^2) + c^2 \left(\frac{u}{c} \cos \theta \right)^2 \quad (3)$$

where T is the temperature of the gas stream. (For the sake of simplicity, let us consider the case of a gas stream, $\theta = 0$, then

$$E_{i_{hr}} = \rho \frac{c}{2\sqrt{\pi}} (c^2 + \frac{1}{2} u^2), \quad \theta = 0$$

The total incident energy per unit area is then

$$E_i = \rho \frac{c}{2\sqrt{\pi}} \left[\frac{1}{2} u^2 + (\frac{1}{2} R + C_v) T \right] \quad (4)$$

where E_0 is the specific heat of the gas at constant volume of T_w is the wall temperature, and α the accommodation coefficient, the difference between the energy incident at the surface and the energy E_0 carried by the molecules as it left the surface is given by

$$E_0 - E_i = \alpha(E_i - E_w)$$

where E_i is the energy that would be carried away by the molecules if the surface were at the temperature of the wall T_w .

where $E_i = \alpha p \frac{\sqrt{\pi} RT}{4\sqrt{2\pi}} \left\{ \left(\frac{1}{2} R + C_v \right) (T - T_w) + \frac{1}{2} U^2 \right\}$ (11)

the energy radiated from the surface is $\epsilon \sigma T_w^4$ where ϵ is the emissivity, and σ the Stefan-Boltzmann constant.

For the hot wire to be a thermistor, the energy balance requires

$$\frac{E_i}{r} = \epsilon \sigma T_w^4 + \frac{E_0}{r} \quad (12)$$

If p is the temperature coefficient of the resistance of the wire and r_0 is the resistance at temperature T_0 , then

$$r = r_0 [1 + \beta(T - T_0)] \quad (12)$$

where r_0 is the resistance of the wire at the ambient temperature T_0 . If T_w is equal to T_0 from (11) and (12), we have

$$\frac{E_i}{r_0} = \frac{1}{2\gamma} \frac{\gamma+1}{\gamma-1} \left(\frac{E_0}{r_0} \right) \left(\frac{r}{r_0} - 1 \right) + \left[\frac{\epsilon \sigma T_w^4}{\alpha p \frac{\sqrt{\pi} RT}{4\sqrt{2\pi}}} \right] \left(1 + \frac{r}{r_0} \right) \left(\frac{r}{r_0} \right)^{\frac{1}{\gamma-1}}$$

$$\left[\frac{E_0}{r_0} \frac{1}{\alpha p \frac{\sqrt{\pi} RT}{4\sqrt{2\pi}}} \right] \left(\frac{r}{r_0} \right)$$

where M is the Mach number of the gas stream, γ is not the specific heat ratio, but the adiabatic exponent of the hot wire.

as the f force the heat from the walls of the test chamber is absent but there may be solar radiation and the radiation from the earth and surrounding atmosphere (14) is also present. Thus the heat flux q from the prototype is

$$q = \left[\frac{\epsilon \sigma T_w^4 - q_{\text{atm}}}{\epsilon \sigma (T_p^4 - T_w^4)} \right] \quad (16)$$

in order for the flow to be same also with a hot model, we must have,

$$q = q_p \quad (17)$$

From eq. (16) and (17) we can write the following relation for the prototype and model

$$\frac{\epsilon \sigma T_w^4 - q_{\text{atm}}}{\epsilon \sigma T_w^4} = \frac{L_p}{L_m} \quad (18)$$

where L_p is the typical linear dimension of the prototype and L_m is the typical linear dimension of the model. If the wall temperature of the test chamber is the same for both, then eq. (18) satisfies (18).

There are other conditions for model testing in a wind tunnel. It is certainly difficult to satisfy all the conditions. One can be relaxed and if the flow is turbulent, then the model can be used.

Problem

Let f_1 and f_2 be functions f_1 and f_2

on the interval $[a, b]$

$$f_1(x) = \frac{1}{\sqrt{x}} \quad f_2(x) = \frac{1}{x^2}$$

$$f_1'(x) = -\frac{1}{2} x^{-3/2} \quad f_2'(x) = -2x^{-3}$$

Let F_1 and F_2 be the antiderivatives of f_1 and f_2 respectively.

Find the value of

$$F_1(b) - F_1(a) + F_2(b) - F_2(a)$$

by the definite integral

$$\int_a^b (f_1(x) + f_2(x)) dx$$

which can be evaluated by partial integration

$$f_1(x) = \frac{1}{\sqrt{x}} \quad f_2(x) = \frac{1}{x^2}$$

$$f_1'(x) = -\frac{1}{2} x^{-3/2} \quad f_2'(x) = -2x^{-3}$$

$$= \frac{1}{\sqrt{x}} + \frac{2}{x^2} = \frac{1}{\sqrt{x}} + \frac{2}{x^2}$$

hence

$$F_2(z) = \sqrt{\eta} z^2 e^{-\frac{z'}{2}} \left[I_0\left(\frac{z'}{2}\right) + I_1\left(\frac{z'}{2}\right) \right]$$

where I_1 is the modified Bessel function of first kind and order 1.

Wind-Tunnel Testing Problems and Principles

Hsue-shen Tsien

Guggenheim Aeronautical Laboratory

Massachusetts Institute of Technology

Wind-tunnels are, perhaps, the most useful tool in aerodynamic investigation and certainly have contributed much to the modern development of fluid mechanics. It is thus natural, when one turns to a new field of aerodynamics, the aerodynamics of rarefied gases or supersonic dynamics, that one should think of using the wind tunnel again. Only here it has to be adapted to entirely new circumstances and new problems, and in its design and in its operation, appear. It is the purpose of this paper to discuss some of these problems, so as to gain an orientation in the new field of experimentation.

1. Tunnel Design

To test models in the wind tunnel at its test section, it is of primary importance to obtain a uniform stream at the desired temperature, pressure and velocity. For a sonic wind tunnel at ordinary pressures, this can be achieved without much difficulty. For a supersonic wind tunnel at ordinary pressure, the expansion part of the nozzle of the test section or the nozzle is first designed to obtain a uniform stream at its exit without considering the effects of the viscosity of air. Then the boundary layer along the wall of the nozzle is calculated with the pressure gradient thus determined. Hence, the displacement thickness of the boundary layer, or the needed space of the boundary layer, is determined. The velocity is provided

COPY

ed by making the nozzle larger than the dimension first determined by the calculated amount. (Ref. 1) This design procedure is found to give satisfactory nozzles for supersonic wind tunnels.

However when one tries to use the same design procedure for the supersonic aerodynamic wing tunnel, one is immediately confronted with the difficulty of extremely large viscous effects. In other words, the boundary layer will be so thick as to occupy the main portion of the test passage. To demonstrate this effect, let the length of the test section be L and the width of the square test section be b . Then the Reynolds number based upon the conditions in the test section is $Re = \frac{U b}{\nu}$ where U is the velocity in the test section. If, as a rough estimate, we take the thickness of the boundary layer to be zero at the beginning of the test section and equal to a value calculated by the von Karman law as $\delta = 3.65 L / \sqrt{Re}$ at the end of the test section, then

$$\delta = 3.65 L / \sqrt{Re} \quad (1)$$

Now if this boundary layer actually occupies half the test section, then

$$\delta = \frac{b}{2} = 3.65 L / \sqrt{Re} \quad (2)$$

On the other hand, the ratio of the mean velocity \bar{u} to the boundary layer thickness δ is known (Ref. 2) to be equal to

$$\frac{\bar{u}}{\delta} = \frac{1.255 \sqrt{\gamma}}{3.65} \frac{M}{\sqrt{Re}} \quad (3)$$

where γ is the ratio of specific heats and M is taken as M_1 , the Mach number in the test section. By combining (2) and (3), we have

$$\left(\frac{\bar{u}}{\delta} \right) \left(\frac{L}{b} \right) = 0.0557 M \quad (4)$$

This relation is known as $\lambda = 1$. The Mach number equal to 1, and $L/b = 2$, the boundary layer will extend all up the test section, if the mean free path is equal to 5.6% of the boundary layer thickness or 1.8% of the tunnel width. This means that the extremely thin layer of free air low velocities makes the entire tunnel section as a wind tunnel totally inapplicable.

The extremely thick boundary layer where the velocity increases from a small value near the wall to some supersonic velocity at the center of the nozzle, also gives some air velocity in the center of the nozzle. Since pressure distribution is a function of the velocity in subsonic flows, the flow in the test section of a low pressure tunnel will be sensitive to changes in the diffuse even if the main stream velocity at the center of the nozzle is supersonic. This is of course a new phenomenon in supersonic flow.

The large viscous effects can be also demonstrated by calculating the ratio of frictional loss on the walls of the test section and the shock loss in the diffuser after the test section. Consider a diffuser of a straight tube of approximately the same cross sectional area as the test section, then the pressure loss due to friction is

$$\Delta p_f = \frac{4 C_f L U^2}{b}$$

Taking C_f to be Blasius value or $C_f = \frac{1.328}{\sqrt{Re}}$ we have

$$\Delta p_f = 2 \rho U^2 \left(\frac{L}{b} \right) \frac{1.328}{\sqrt{Re}} \quad (5)$$

COPY

Now if p_0 is the static pressure in the test section, then the pressure rise by ideal isentropic compression in the diffuser is $p_0(p_0/p_1)^{1/\gamma}$. If the actual pressure rise in the diffuser is estimated as $p_0(p_0/p_1)^{1/\gamma}$ due to a normal shock without further recovery, then the actual pressure rise is

Therefore the pressure loss due to shock is

(6)

By combining (5) and (6), the ratio of these two pressure losses is

(7)

Introducing the mean free path ratio given by (3), we have

(8)

This relation is plotted in Fig. 2. Therefore if the Mach number is 2, and $L/b = 2$ as before, then when the ratio $(\mu/\rho U)$ is 0.056, the ratio of frictional loss to shock loss is 0.428. Hence the frictional loss and the shock loss is of the same order of magnitude.

These large viscous effects are fully confirmed by the recent tests on the 1" x 1" low pressure wind tunnel at the University of California.* The test nozzle (Fig. 3), was designed for Mach number 2 with no consideration of the viscous effects in the medium. During test, the static pressure on the

* Experimental work done under contract with the Office of Naval Research.

The author is deeply indebted to Professors R. G. Folsom and E. D. Kane for permission to use their unpublished results.

COPY

wall at the exit of the nozzle is measured. This pressure is equal to 176 microns* for the two tests presented in Figs. 4 and 5. The apparent Mach number "M" is the Mach number calculated from the dynamic pressure measured by a Pitot tube using the following formula. Since there is the complication of large viscous effect in the Pitot tube reading as shown in the following section, this apparent Mach number is only quantitative and cannot be taken as the exact value. However it is apparent from Figs. 4 and 5 that the boundary layer in the test section is indeed very thick, and fills up the whole space. This large boundary layer thickness makes this space available for the expansion of the central potential flow if it exists, very small. Therefore the maximum Mach number reached at the center of the nozzle is very much smaller than the design Mach number of 4. At the lower pressure, the influence of slip at the wall is also evident. This has the tendency to make the flow more uniform. However the very low Mach number at the test section indicates again the strong viscous effect in converting such a high pressure energy into heat energy.

These elementary calculations and preliminary test results makes it clear that for the design of the nozzle and test section for a supersonic wind tunnel, it is no longer possible to separate the compressibility effects and the viscous effects. In fact, the concept of boundary layer is also of doubtful value due to the extremely small Reynolds number encountered. Therefore to actually design such a nozzle to obtain the nearest approximation to the ideal uniform flow it will be necessary to use the exact Navier Stokes equations instead of the approximate inviscid Euler equations. Of course, it may be argued that for supersonic flows, the Navier-Stokes equations for no more exact and additional corrections must be added (Ref. 2). However, recent investigations by

* 1000 microns = 1 mm Hg, one atmosphere = 0.760×10^6 microns.

COPY

R. Schamberg Ref. 4 have shown that these additional corrections are small in case of slip-flows concerned here and will not essentially alter the flow pattern. Hence for a first approximation just like the non-viscous isentropic flow as a first approximation for ordinary supersonic nozzles, we can use the Navier-Stokes equations. The simplest case to be considered is certainly the axially symmetric nozzles. If x is the coordinate in the axial direction, r the coordinate in the radial direction and u and v are the corresponding velocity components, the equations are:

(9)

(10)

(11)

(12)

where

ϵ = dissipation function

σ = stresses tensor

(9), (10), (11) and (12) together with the equation of states

$$p = R T \quad (13)$$

then determines ρ as a function of u , v , r , and T . Of course, the actual process of making this calculation will be extremely tedious and some approximation method of solution may have to be developed. The possibility would be to adopt

the Karman boundary layer theory. We integrate the differential equations with respect to r and thus only try to satisfy the equations "on an average" over the cross section of the nozzle. The "distribution" of u, v over the cross-section will then be set in the form of a polynomial. Initial data in this procedure is already made by B. A. Schaaf (Ref. 4) at the suggestion of the author.

For ordinary supersonic flow, high efficiency pressure recovery can be generated by a well designed diffuser. However, for a supersonic wind tunnel, due to the extremely large loss through friction, long diffusers are necessary. In fact, the pressure loss can be reduced by using a shortest possible diffuser.

2. Flow Measurement

The quantities which determine the flow field are two out of the three variables ρ, p, T and the velocity components. The quantities ρ, p, T are related by the equation of states and therefore only two is necessary for the determination of a flow. Generally, in wind tunnel work, the quantities ρ, p, T are measured and the magnitude of the velocity.

For the measurement of pressure, a manometer is used. For ordinary pressure, the manometer fluid is water, alcohol or mercury. However, for supersonic flow, pressure is measured in the supersonic flow, some special care is necessary. The most successful type is the Pitot-static probe. It utilizes the change in pressure of a wire heated with an electric current. A change in the pressure of the gas surrounding it. The temperature change is measured by the resistance of the wire. The wire is heated in a small chamber which is connected to the

COPY

point of measurement of the static pressure is to be measured. The question of best design of the connecting tube for quick response is studied by S. A. Schaaf. (Ref. 5).

To measure the density, the conventional method utilizes the difference in the velocity of the light rays in media of different density. With different optical arrangements we have the shadowgraph method, the schlieren method and the interferometer method. However, if the density of the medium is very low as the case of a free dynamic flow, the sensitivity of these methods is low. In the case of the schlieren method, the percentage change in the refraction index by passing through a region of thickness b is given by

$$(14)$$

where ρ_0 is the air density at 32°F and 1 atmosphere pressure, and $\frac{d\rho}{dx}$ is the density gradient normal to the light ray. l and w are the local length and width of the light source image perpendicular to the knife edge. k is a constant, determined by the particular optical path used. Therefore the sensitivity of the schlieren method decreases with the factor $\frac{1}{l^2 w}$. Some improvement can be made by altering the quantities l and w , but the practical limitations and fabrication difficulties do not allow the increase of sensitivity to satisfactory values.

A new method for the problem density measurement is the method of absorption. It is known, for instance, that oxygen at low pressure shows a strong absorption around 1.27×10^{-6} A or ultra violet light. The percentage absorption is proportional to the number of molecules that meet the light ray and is, therefore, proportional to the density of the gas. The measurement is then similar to that of the interferometer method where the density is determined. A similar method is the utilization of the after-flow of nitrogen. These

COPY

methods are now being studied by L. A. Evans (Ref. 1).

The conventional method for the measurement of velocity is through the use of dynamic pressure rise in a Pitot-tube. A straight forward application of this method is, however, difficult for rarefied gases. The formula used is, however, based upon the neglect of viscosity effects. But for rarefied gases the viscosity effect is of great importance as pointed out in the previous section. Then the dynamic pressure would be quite different than that given by the usual formula. To estimate this effect, let us consider the case of low Mach numbers so that compressibility effects can be neglected. Then as a first approximation, take the flow field around the Pitot tube as that of a source of strength in a non-viscous flow of uniform velocity U . The "radius" of the tube is

$$a =$$

and the stagnation point is located at

(15)

The velocity introduced by the source is then

By subtracting the viscous stress from this approximate disturbance velocity, we have for flow along the axis

(16)

Hence if p_0 is the stagnation pressure and p the static pressure,

Or

1)

COPY

For rarefied gases, the value of $\frac{1}{Re}$ or the reciprocal of the Reynold's number of the Pitot-tube will be of the order of unity. Then the dynamic pressure rise Δp is not the usual values $\frac{1}{2} \rho V^2$ but a value much less than that. In fact previous investigation by Baker (Ref. 7) and F. Hohmann (Ref. 8) indicate that the Reynolds number $Re = \frac{\rho V a'}{\mu}$ where a' is the radius of the mouth of tube, must exceed 20 in order to reach the usual dynamic pressure rise $\frac{1}{2} \rho V^2$.

When the velocity of flow is high, we have the added complication due to the shock. The conventional Rayleigh formula for Pitot tubes is supersonic flow is based upon the assumption that the shock wave ahead of the Pitot tube. Now it is known that the shock is proportional to the mean free path. In rarefied flows, the thickness of the shock will be so increased as to cause interference with flow in the neighborhood of the Pitot-tube. This together with the viscous effect mentioned in previous paragraph definitely show the inapplicability of the Rayleigh formula for supersonic velocity of rarefied gases.

3. Hot-Wire Anemometer

With the great complications in applying the conventional velocity measuring device to supersonic flows, one is naturally led to the thought of other avenues of approach. One possibility is the use of hot-wire. If the wire diameter is of the order of 0.001 inches, and if the pressure of the gas stream is approximately 100 microns, the ratio of the mean free path to the wire diameter will be approximately 100. Therefore the flow around the wire is definitely the free molecule flow (Ref. 9). We have thus a simple physical situation, which is an improvement over the rather uncertain circumstances involved dynamic and viscous effects for the measurement of velocity by Pitot tube. It thus seems worthwhile to explore this possibility by a trial calculation of the performance of such a hot-wire anemometer.

COPY

If θ is the inclination of the solid surface to a gas stream which has a macroscopic velocity U and a Maxwellian molecular velocity distribution, the translational energy of molecules incident upon the unit area is,

(18)

where $c^2 = RT$, T temperature of the gas stream and erf is the error function. Now let r be the radius of the hot-wire. Then the total energy E_t incident upon a unit length of the wire is the sum of translational energy and internal energy. If C_v is the specific heat at constant volume, this total energy per unit length of wire is

(19)

The integrals in equation (19) can be expressed in terms of tabulated functions, (see Appendix) Thus

(20)

where

(21)

(22)

The I_0 and I_1 are the modified Bessel functions of the first kind of orders zero and one respectively. The functions F_1 and F_2 are tabulated in Table 1.

If T_w is the wall temperature, and α the accommodation coefficient, the

COPY

difference between the energy E_i incident upon the surface and the energy E_r carried by the molecules re-emitted from the surface is given by

$$E_i - E_r = (E_i - E_w)$$

where E_w is the energy that would be carried away by the molecules if the re-emission were at the temperature T_w of the wire. Therefore

$$E_i - E_r = c r \left[\frac{1}{2} U^2 + \left(\frac{1}{2} R + C_v \right) (T - T_w) F_1 \left(\frac{U}{C} \right) \right. \\ \left. + \frac{1}{2} U^2 + (R + C_v) (T - T_w) F_2 \left(\frac{U}{C} \right) \right] \quad (23)$$

This difference of energy is then the net energy input to the wire per unit length of the wire by the air stream.

If i is the electric current heating the wire and R is the resistance of the wire per unit length at the wire temperature, the heat input per unit length of wire by the heating current is $i^2 R$. Heat is lost from the wire by radiation. If σ is Stefan-Boltzmann constant and ϵ is the emissivity of the wire surface, the radiation heat loss per unit length is $\epsilon \sigma \pi d (T^4 - T_w^4)$. Therefore if the wire has reached a steady condition, the heat balance requires

(24)

This equation can be put into somewhat simpler form by using the relation that

$$R = C_p - C_v = C_v (\gamma - 1) \quad (25)$$

COPY

Let $R = R_0 [1 + \alpha(T - T_0)]$ where R_0 is a constant which the resistance is R_0 at the temperature T_0 , and the corresponding temperature coefficient of the resistance is α . Then the resistance can be expressed as

$$R = R_0 [1 + \alpha(T - T_0)] \quad (26)$$

Now let

$$T = T_0 + \frac{1}{\alpha} \left(\frac{I}{I_0} - 1 \right) \quad (27)$$

Then from equation (24),

$$\frac{I}{I_0} = \frac{-1}{T_0} + 1 \quad (28)$$

Now introduce ρ_0 as the reference density and i_0 as the reference heating current, then equation (24) can be written as

$$(29)$$

The particular values of the reference temperature T_0 , the reference density ρ_0 and the reference current i_0 are not yet fixed. We fix these quantities now by requiring that

$$T_0 = 1 \quad (30)$$

$$(31)$$

and

$$(32)$$

COPY

Then equation (29) simplifies to

(33)

This is then the performance equation of the hot wire in free molecular flow.

Now let us investigate in greater detail the case of a straight platinum wire. To satisfy equation (30),

$$T_0 = 492^\circ \text{R.}$$

The value for β and γ can be taken to be 0.08 and 0.40 respectively. Then equation (1) gives the corresponding pressure p_0 for β and T_0 as

Let the radius r of the wire be 0.0001 inch. Then equation (3) gives the reference heating current i_0 as

$$i_0 = \frac{1}{\sqrt{R}} = 0.274 \text{ milliamperes.}$$

where the resistivity of the platinum is taken as 10.9×10^{-6} ohm-cm. Therefore the order of magnitude of the different quantities is entirely satisfactory.

If the wire is used with a constant heating current, then equation (3) can be used to calculate the relation between the resistance ratio and the velocity ratio $\left(\frac{V}{C}\right)$ at constant air stream density and temperature. This is true for $\beta_0 = 1$, $T/T_0 = 1$ and $i/i_0 = 1$ and the result is given in Fig. 5. It is seen that the sensitivity of the instrument is good. Of course, the behavior of the hot-wire anemometer will be actually determined by calibration for any experiment.

* The author is indebted to Mr. L. Mack for the numerical computations.

COPY

above the wall is the same. These considerations lead to indicate that for the model test to be similar to the prototype, the model must be made of same surface material as the prototype, and the fluid must be the same, and furthermore the following parameters must be the same:

- (1) Reynolds number Re
- (2) Mach number M^0
- (3) free stream temperature T^0

The radiation heat loss from the surface is equal to $\epsilon \sigma (T_s^4 - T_w^4)$ per unit area. However, if the model is surrounded by the walls of the test chamber, there is also an heat input due to radiation from walls of the test section to the model. Let us call this quantity q_{rad} . Then the net heat loss per unit area of the surface of the model is $\epsilon \sigma (T_s^4 - T_w^4) - q_{rad}$. This quantity can be rendered non-dimensional by dividing it by σT^0^4 . Call this new parameter ϵ^* , then

(34)

For the prototype, the heat from the walls of the test chamber is a heat input there may be solar radiation and the radiation from the earth and surrounding atmosphere. (Ref. (3)). Denoting this amount by $q_{rad,p}$, then the parameter for the prototype is

(35)

In order for the flow to be same also with respect to the radiative heat transfer,

(36)

Because of the previous conditions on the Reynolds number and free stream temperature, (36) is the same as

COPY

Since the performance of the wire is strongly influenced by the accommodation coefficient as shown by equation (29), it will be necessary to find materials which can hold this coefficient constant for a considerable period of time so that no frequent calibration is required. However the present analysis seems to indicate the feasibility of such an instrument for measurements in rarefied gases and further research is definitely desirable.

4. Parameters of Flow

The two parameters that are directly connected with the flow field are the Reynold's number Re , defined as

$$Re = \frac{U L}{\nu}$$

where ν is the kinematic viscosity, L the typical linear dimension of the body, and the Mach number M^0 of the free stream. This is true even for slip flows and free molecule flows due to the fact that the ratio of mean free path to typical dimension can be also expressed in terms of the Reynold's number and the Mach number.

However, as the pressure or density is reduced, the solid boundary of the flow enters actively into the flow conditions by requiring not only that the microscopic stream velocity be tangential to the surface but that the interaction of the molecules and the wall be considered and that the radiation of energy to and from the wall be taken into account. The interaction of the molecules with the wall is so far expressed through the fraction α of molecules that are diffusely re-emitted from the wall, and the accommodation coefficient γ . It is known that both α and γ are functions of the temperature of the wall and we have reasons to believe that they are also functions of the molecular velocity distribution. Therefore the interaction of the molecules with the wall is the same only if the wall temperature, the gas temperature and the Mach number of the gas

Dear Mr. Dexter:

Enclosed are two manuscripts which I am submitting for consideration of publication in the Journal of the Aeronautical Sciences.

The first paper, "Wind-Tunnel Testing Problem in Superaerodynamics", is the revised form of my paper presented in the Annual Meeting. I apologize for the long delay in getting the manuscript into this form.

The second paper, "Two Dimensional Airfoils in Hypersonic Flow", is written by Mr. Richard D. Linnell and is taken from his Thesis at the Massachusetts Institute of Technology.

Very sincerely yours

Dear Dr. Tsien:

We are now preparing your paper, "Wind-Tunnel Testing Process in Supersonic Flow," for publication, and there does not seem to be an abstract or summary included. Since we feel that some sort of an abstract should be published with the paper, I should appreciate your sending one as soon as possible.

Very truly yours,

Wind-Tunnel Testing Problems in Superaerodynamics

Hsue-shan Tsien

Summary

The problems in the experimentation of rarefied gas are discussed. First the extremely large viscous effects in a wind-tunnel nozzle is shown. Then the difficulties of flow measurement are surveyed, pointing out particularly the unconventional behavior of the Pitot tube in rarefied gas. The performance of a hot-wire anemometer is then studied in some detail to show its feasibility. Finally the rules for achieving complete flow similarity of rarefied gas flow are formulated.

Section 2

Hypersonic Flows $M_\infty \gg \infty$

Hypersonic Flow $M_1 \rightarrow \infty$

(I) Two Dimensional Case

a) The inclined shock

$$\tan \beta = \tan \alpha \cdot \frac{\gamma-1}{\gamma+1}$$

$$p_2 = \frac{2}{\gamma+1} \rho_1 v_1^2 \sin^2 \alpha$$

$$M_2^2 = (1 + \cot^2 \beta) \frac{\gamma-1}{2\gamma} = \left\{ 1 + \cot^2 \alpha \cdot \left(\frac{\gamma+1}{\gamma-1} \right)^2 \right\} \frac{\gamma-1}{2\gamma}$$

$$M_2^2 = \frac{\gamma-1}{2\gamma} \frac{1}{\tan^2 \alpha} + \frac{2}{\gamma-1} \cot^2 \alpha$$

$$= \frac{\gamma-1}{2\gamma} \frac{1}{\tan^2 \alpha} + \frac{2}{\gamma-1} \left[\frac{1}{\tan^2 \alpha} - 1 \right]$$

$$M_2^2 = \frac{(\gamma+1)^2}{2\gamma(\gamma-1)} \frac{1}{\tan^2 \alpha} - \frac{2}{\gamma-1}$$

$$\cot \beta = \cot \alpha \left(\frac{\gamma+1}{\gamma-1} \right)$$

b) Subsequent Expansion

We shall use the formula

$$\frac{1}{1 \pm \frac{1}{2} M^2} = \frac{1}{1 \pm \frac{1}{2} M^2} = \frac{1}{1 \pm \frac{1}{2} M^2} \approx 1 \mp \frac{1}{2} M^2 + \frac{1}{8} M^4 - \dots$$

$$\frac{1}{1 \pm \frac{1}{2} M^2} \approx 1 \mp \frac{1}{2} M^2 + \frac{1}{8} M^4 - \dots$$

$$= \left[\frac{1}{2} - \frac{1}{\sqrt{M^2-1}} + \frac{1}{3} \frac{1}{(M^2-1)^{3/2}} - \dots \right]$$

$$\frac{1}{1 \pm \frac{1}{2} M^2} \approx \frac{1}{1 \pm \frac{1}{2} M^2} \approx \frac{1}{1 \pm \frac{1}{2} M^2}$$

$$+ \left[\frac{1}{2} - \frac{1}{\sqrt{M^2-1}} + \frac{1}{3} \frac{1}{(M^2-1)^{3/2}} - \dots \right]$$

$$\frac{1}{1 \pm \frac{1}{2} M^2} \approx \frac{1}{1 \pm \frac{1}{2} M^2} \approx \frac{1}{1 \pm \frac{1}{2} M^2}$$

We have the formula

$$1 + \frac{1}{2} M^2 = \left(\frac{p_1}{p} \right)^{\frac{1}{\gamma}}, \quad 1 + \frac{1}{2} M_2^2 = \left(\frac{p_2}{p} \right)^{\frac{1}{\gamma}}$$

Our aim is to express p/p_2 in terms of $\theta_0 - \theta$.

$$\frac{1 + \frac{1}{2} M^2}{1 + \frac{1}{2} M_2^2} = \left(\frac{p_2}{p} \right)^{\frac{1}{\gamma}}$$

$$r_0 = \frac{2}{\gamma-1} \frac{1}{M_2^2} \left(1 - \frac{M_2^2}{M_1^2} \right) \left(\frac{1}{3} \frac{\gamma-1}{\gamma+1} \frac{1}{M_2^2-1} \right) \left(1 - \frac{M_2^2}{M_1^2} \right)$$

$$\gamma_1 = \frac{1}{M_2^2-1} \left(1 - \frac{M_2^2}{M_1^2} \right) \left(\frac{1}{3} \frac{\gamma-1}{\gamma+1} \frac{1}{M_2^2-1} \right) \left(1 - \frac{M_2^2}{M_1^2} \right)$$

$$\frac{L_1}{M_2^2} + \frac{L_2}{M_2^2} = \frac{L_1}{M_1^2}$$

$$\frac{L_1}{M_2^2} + \frac{L_2}{M_2^2} = \frac{L_1}{M_1^2} \left(\frac{M_1^2}{M_2^2} \right)^{\frac{\gamma-1}{\gamma}} \left(\frac{M_1^2}{M_2^2} \right)^{\frac{\gamma-1}{\gamma}} = \frac{L_1}{M_1^2} \left(\frac{M_1^2}{M_2^2} \right)^{\frac{2(\gamma-1)}{\gamma}}$$

$$\frac{L_1}{M_2^2} = \left(\frac{2}{(\gamma-1)M_2^2} + 1 \right) \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} - \left(\frac{M_1^2}{M_2^2} \right)^{\frac{1}{\gamma-1}}$$

$$= \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} + \frac{1}{\gamma-1} \left(2 \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} - (\gamma+1) \right) \frac{1}{M_2^2}$$

$$= \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} \left[1 + \frac{1}{\gamma-1} \left(2 - (\gamma+1) \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma-1}{\gamma}} \right) \frac{1}{M_2^2} \right]$$

$$\frac{L_1}{M_2^2} = \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} \left[1 - \frac{\gamma+1}{\gamma-1} \left(1 - \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma-1}{\gamma}} \right) \frac{1}{M_2^2} \right]$$

$$= \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma}{\gamma-1}} \left[1 - \frac{\gamma+1}{\gamma-1} \left(1 - \left(\frac{L_1}{M_1^2} \right)^{\frac{\gamma-1}{\gamma}} \right) \frac{1}{M_2^2} \right]$$

$$\theta_2 = 0 = \frac{2}{j+1} \frac{1}{H_2} \left\{ 1 + \frac{1}{2} \frac{1}{H_2^2} \left[\left(1 - \left(\frac{k}{k_2} \right)^{\frac{j+1}{2}} \right) \left(1 - \frac{1}{2} \frac{1}{j+1} \left(1 - \left(\frac{k}{k_2} \right)^{\frac{j+1}{2}} \right) \frac{1}{H_2^2} \dots \right) \right] \right\}$$

$$- \frac{1}{3} \frac{1}{j+1} \frac{1}{H_2^2} \left\{ 1 - \left(\frac{k}{k_2} \right)^{\frac{j+1}{2}} \right\} \dots \right]$$

$$= \frac{1}{3} \frac{1}{j+1} \left[1 - \left(\frac{k}{k_2} \right)^{\frac{j+1}{2}} \right] \left\{ \frac{1}{H_2^2} \right\}$$

(c) Small θ_0

$$\tan(\alpha + \theta_0) = \frac{k-1}{k+1} \tan \alpha$$

$$1 + \tan \alpha \tan \theta_0 = \frac{k+1}{k-1}$$

$$\tan \alpha + \tan \theta_0 = \frac{k-1}{k+1} \tan \alpha + \frac{k-1}{k+1} \tan^2 \alpha \tan \theta_0$$

$$\tan \alpha = \tan \theta_0 + \frac{k-1}{k+1} \tan^2 \alpha \tan \theta_0$$

$$\frac{k}{(k+1)^2} \frac{\tan \alpha}{1 - \tan^2 \alpha} = \tan^2 \theta_0 + 2 \frac{k-1}{k+1} \tan^2 \theta_0 \frac{\tan^2 \alpha}{1 - \tan^2 \alpha} + \left(\frac{k-1}{k+1} \right)^2 \tan^2 \theta_0 \frac{\tan^4 \alpha}{(1 - \tan^2 \alpha)^2}$$

$$\frac{4}{\gamma+1} [\sin^2 \alpha - \sin^4 \alpha] = \tan^2 \theta_0 \left[1 - 2 \sin^2 \alpha + \sin^4 \alpha \right] + 2 \frac{\gamma-1}{\gamma+1} \sin^2 \alpha \sin^2 \alpha$$

$$+ \left(\frac{\gamma-1}{\gamma+1} \right)^2 \tan^2 \theta_0 \sin^4 \alpha$$

$$\left[1 - \frac{\gamma-1}{\gamma+1} \tan^2 \theta_0 + \frac{\gamma-1}{\gamma+1} \sin^4 \alpha + \left[1 - 2 \frac{\gamma-1}{\gamma+1} \tan^2 \theta_0 + \left(\frac{\gamma-1}{\gamma+1} \right)^2 \tan^2 \theta_0 \right] \sin^2 \alpha \right. \\ \left. + \tan^2 \theta_0 = 0 \right]$$

$$\left(\frac{\gamma-1}{\gamma+1} \right)^2 (\tan^2 \theta_0 + 1) \sin^4 \alpha - 2 \frac{\gamma-1}{\gamma+1} \left[\tan^2 \theta_0 + \frac{1}{\gamma+1} \right] \sin^2 \alpha + \tan^2 \theta_0 = 0$$

$$(\tan^2 \theta_0 + 1) \sin^4 \alpha - 2 \left(\frac{\gamma-1}{2} \right) \left[\tan^2 \theta_0 + \frac{1}{\gamma+1} \right] \sin^2 \alpha + \left(\frac{\gamma-1}{2} \right)^2 \tan^2 \theta_0 = 0$$

$$\sin^2 \alpha = \cos^2 \theta_0 \left[\frac{\gamma-1}{2} \tan^2 \theta_0 + \frac{1}{2} - \sqrt{\frac{1}{4} - \frac{\gamma-1}{4} \tan^2 \theta_0} + \dots \right]$$

$$- \left(\frac{\gamma-1}{2} \right)^2 \tan^4 \theta_0 - \left(\frac{\gamma-1}{2} \right)^4 \tan^6 \theta_0$$

$$= \cos^2 \theta_0 \left[\frac{\gamma-1}{2} \tan^2 \theta_0 + \frac{1}{2} - \sqrt{\frac{1}{4} - \frac{\gamma-1}{4} \tan^2 \theta_0} \right]$$

$$= \frac{1}{2} \cos^2 \theta_0 \left[(\gamma+1) \tan^2 \theta_0 + 1 - \sqrt{1 - (\gamma^2-1) \tan^2 \theta_0} \right]$$

$$\frac{1}{2} \cos^2 \theta_0 \left[\tan^2 \theta_0 + \chi - \chi + \frac{\gamma-1}{2} \tan^2 \theta_0 + \frac{1}{\gamma+1} \right] = \dots$$

$$\sin^2 \alpha = \left(\frac{\gamma-1}{2} \right)^2 \sin^2 \theta_0 + \frac{1}{16} (\gamma^2-1)^2 \sin^4 \theta_0 \tan^2 \theta_0 \dots$$

$$\sin \theta_0 = \theta_0 \left(1 - \frac{1}{6} \theta_0^2 \dots \right)$$

$$\sin^2 \theta_0 = \theta_0^2 \left(1 - \frac{1}{3} \theta_0^2 \dots \right),$$

$$\sin^2 \alpha = \left(\frac{\gamma+1}{2}\right)^2 \left[\theta_0^2 \left(1 - \frac{1}{3} \theta_0^2 \dots\right) + \frac{1}{4} (\gamma-1)^2 \theta_0^4 \dots \right]$$

$$\sin^2 \alpha = \left(\frac{\gamma+1}{2}\right)^2 \theta_0^2 \left[1 - \left\{ \frac{1}{3} - \left(\frac{\gamma-1}{2}\right)^2 \right\} \theta_0^2 \dots \right]$$

$$\frac{1}{M_2^2} =$$

$$\frac{1}{\gamma_1} \frac{\gamma_1^2}{\gamma_1^2} \dots = \frac{1}{\gamma_1}$$

$$\sin^2 \alpha$$

$$\sin^2 \alpha$$

$$\frac{1}{M_2^2} = \frac{1}{\gamma_1} \frac{\gamma_1^2}{\gamma_1^2} \dots = \frac{1}{\gamma_1}$$

$$\frac{1}{M_2^2} = \frac{\gamma(\gamma-1)}{2} \theta_0^2 \left[1 - \left\{ \frac{1}{3} - \left(\frac{\gamma-1}{2}\right)^2 \right\} \theta_0^2 \dots \right] \left[1 + \gamma \theta_0^2 \dots \right]$$

$$\frac{1}{M_2^2} = \frac{\gamma(\gamma-1)}{2} \theta_0^2 \left[1 + \left\{ \gamma + \left(\frac{\gamma-1}{2}\right)^2 - \frac{1}{3} \right\} \theta_0^2 \dots \right]$$

$$\frac{1}{M_2^2} = \gamma \frac{\gamma-1}{2} \theta_0^2 \left[1 + \frac{1}{3} \left\{ \gamma + \left(\frac{\gamma-1}{2}\right)^2 - \frac{1}{3} \right\} \theta_0^2 \dots \right]$$

thus

2

$$\theta_0 - \theta = \sqrt{\frac{2\gamma}{\gamma-1}} \theta_0 \left[1 + \frac{1}{2} \left\{ \gamma + \left(\frac{\gamma-1}{2} \right)^2 - \frac{1}{3} \right\} \theta_0^2 \dots \right]$$

$$\left[1 - \frac{1}{2} \frac{\gamma-1}{\gamma} \frac{1}{4} + \frac{\gamma}{4} \right] = \frac{2+3}{3} + 2 \frac{1}{\gamma} \frac{\gamma-1}{4} - \frac{3-\gamma}{2} \frac{1}{\gamma}$$

there

$$\theta_0 - \theta = \sqrt{\frac{2\gamma}{\gamma-1}} \theta_0 \left[\left(1 - \frac{1}{2} \frac{\gamma-1}{\gamma} \right)^{\frac{\gamma-1}{2\gamma}} + \frac{1}{2} \left(1 + \frac{1}{2} \left\{ \gamma + \left(\frac{\gamma-1}{2} \right)^2 - \frac{1}{3} \right\} \theta_0^2 \dots \right) \right]$$

if $\gamma = 1.4$

$$\theta_0 - \theta = \sqrt{\frac{2\gamma}{\gamma-1}} \theta_0 \left[1 + \left\{ \frac{1}{2} \left[\gamma + \left(\frac{\gamma-1}{2} \right)^2 - \frac{1}{3} \right] - \frac{1}{12} \right\} \theta_0^2 \dots \right] = \theta_0$$

$$\sim \left(\sqrt{\frac{2\gamma}{\gamma-1}} - 1 \right) \theta_0$$

$$\text{if } \gamma = 1.405, \quad \sqrt{\frac{2\gamma}{\gamma-1}} - 1 = 1.632$$

Two-Dimensional Flow

The general differential equation is

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} = 0$$

$$\psi = \psi(x, y)$$

$$\psi = \psi(x, y)$$

$$a^2 = \frac{1}{2} \left[u^2 + 2u \frac{\partial \psi}{\partial x} + \left(\frac{\partial \psi}{\partial x} \right)^2 + \left(\frac{\partial \psi}{\partial y} \right)^2 \right]$$

$$a^2 = a_0^2 - \frac{1}{2} u^2, \quad a_0^2 = a^2 + \frac{1}{2} u^2$$

$$a^2 = a_0^2 + \frac{1}{2} u^2 - \frac{1}{2} \left[u^2 + 2u \frac{\partial \psi}{\partial x} + \left(\frac{\partial \psi}{\partial x} \right)^2 + \left(\frac{\partial \psi}{\partial y} \right)^2 \right]$$

$$\frac{a^2}{a_0^2} = \frac{u^2 + 2u \frac{\partial \psi}{\partial x} + \left(\frac{\partial \psi}{\partial x} \right)^2}{a_0^2 \left[1 - \frac{1}{2} \left(\frac{u^2}{a_0^2} + 2 \frac{u}{a_0^2} \frac{\partial \psi}{\partial x} + \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial x} \right)^2 + \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial y} \right)^2 \right) \right]}$$

$$\frac{a^2}{a_0^2} = \frac{u^2 + 2u \frac{\partial \psi}{\partial x} + \left(\frac{\partial \psi}{\partial x} \right)^2}{a_0^2 \left[1 - \frac{1}{2} \left(\frac{u^2}{a_0^2} + 2 \frac{u}{a_0^2} \frac{\partial \psi}{\partial x} + \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial x} \right)^2 + \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial y} \right)^2 \right) \right]}$$

$$\frac{H'^2 + 2H' \frac{1}{a_0^2} \frac{\partial \psi}{\partial x}}{1 - (\gamma-1) H' \frac{1}{a_0^2} \frac{\partial \psi}{\partial x} - \frac{\gamma-1}{2} \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial y} \right)^2}$$

$$\frac{H'^2 + 2H' \frac{1}{a_0^2} \frac{\partial \psi}{\partial x}}{1 - (\gamma-1) H' \frac{1}{a_0^2} \frac{\partial \psi}{\partial x} - \frac{\gamma-1}{2} \frac{1}{a_0^2} \left(\frac{\partial \psi}{\partial y} \right)^2}$$

Therefore the differential equation becomes

$$H'' \left(\frac{f}{6} \right) \left(\frac{1}{6} \right)^2 \frac{\partial^2 \theta}{\partial \eta^2} + \left[(1-\gamma) H'' \left(\frac{f}{6} \right) \frac{\partial \theta}{\partial \xi} - \frac{1}{2} \left(\frac{\partial \theta}{\partial \eta} \right)^2 - \frac{1}{6} \left(\frac{\partial \theta}{\partial \eta} \right)^2 \right] \frac{\partial^2 \theta}{\partial \eta^2} = 0$$

$$+ \left[(1-\gamma) H'' \left(\frac{f}{6} \right) \frac{\partial \theta}{\partial \xi} - \frac{1}{2} \left(\frac{\partial \theta}{\partial \eta} \right)^2 - \frac{1}{6} \left(\frac{\partial \theta}{\partial \eta} \right)^2 \right] \frac{\partial^2 \theta}{\partial \eta^2} = 0$$

$$+ \left[(1-\gamma) H'' \left(\frac{f}{6} \right) \frac{\partial \theta}{\partial \xi} - \frac{1}{2} \left(\frac{\partial \theta}{\partial \eta} \right)^2 - \frac{1}{6} \left(\frac{\partial \theta}{\partial \eta} \right)^2 \right] \frac{\partial^2 \theta}{\partial \eta^2} = 0$$

$$+ \left[(1-\gamma) H'' \left(\frac{f}{6} \right) \frac{\partial \theta}{\partial \xi} - \frac{1}{2} \left(\frac{\partial \theta}{\partial \eta} \right)^2 - \frac{1}{6} \left(\frac{\partial \theta}{\partial \eta} \right)^2 \right] \frac{\partial^2 \theta}{\partial \eta^2} = 0$$

$$\text{Let } \eta = a \cdot b \cdot \frac{f}{6} \cdot f(\xi, \eta)$$

$$x = 6\xi$$

$$\eta = 6\gamma \left(\frac{f}{6} \right)^2$$

$$\text{Boundary conditions, at } \infty, \quad \frac{\partial f}{\partial \xi} = \frac{\partial f}{\partial \eta} = 0$$

$$\text{At } \eta = 0, \quad \left(\frac{\partial \theta}{\partial \eta} \right)_{\eta=0} = a \cdot H'' \left(\frac{f}{6} \right)$$

$$\therefore \left(\frac{\partial \theta}{\partial \eta} \right)_{\eta=0} = a \cdot H'' \left(\frac{f}{6} \right) \left(\frac{1}{6} \right)^2$$

$$\text{At } \eta = 0, \quad a \cdot b \cdot \frac{f}{6} \left(\frac{\partial \theta}{\partial \eta} \right)_{\eta=0} \cdot \frac{1}{6} \cdot \frac{1}{\left(\frac{f}{6} \right)^2} = a \cdot (H'' \left(\frac{f}{6} \right)) \left(\frac{1}{6} \right)$$

$$\text{Or } \left(\frac{\partial \theta}{\partial \eta} \right)_{\eta=0} = [H'' \left(\frac{f}{6} \right)] [H'' \left(\frac{f}{6} \right)] \left(\frac{1}{6} \right)$$

$$f_{n0} = k \frac{f}{M^2}$$

$$\left[\frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} \right]$$

$$\frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2}$$

$$\frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2} + \frac{f}{M^2}$$

$$p^0 = p_0 \left[1 + \frac{\gamma-1}{2} M^2 \right]^{\frac{\gamma}{\gamma-1}}$$

$$p = p^0 \left[\frac{1 + \frac{\gamma-1}{2} M^2}{M^2 + \gamma M^2 + \frac{\gamma}{2} + \frac{1}{2} \gamma^2} \right]^{\frac{\gamma}{\gamma-1}}$$

$$1 - (\gamma-1) M^2 \frac{1}{2} \frac{\gamma}{\gamma} - \frac{\gamma-1}{2} \left(\frac{1}{2} \frac{\gamma}{\gamma} \right)^2$$

$$p = p^0 \left[1 - (\gamma-1) \frac{\gamma}{2} - \frac{\gamma-1}{2} \left(\frac{\gamma}{2} \right)^2 \right]^{\frac{\gamma}{\gamma-1}}$$

$$\text{Sum} = \int_0^{\infty} \left(\frac{1}{2} \rho \frac{\partial^2 \psi}{\partial x^2} + \rho \frac{\partial \psi}{\partial x} \left[\frac{1}{2} \left(\frac{\partial \psi}{\partial x} \right)^2 + \frac{1}{2} \left(\frac{\partial \psi}{\partial y} \right)^2 \right] \right) dx$$

$$C_L = \frac{D}{\rho U^2 c} = \frac{D}{\rho U^2 c} = \frac{(1/2) \rho U^2}{\rho U^2 c} \int_0^{\infty} \left[(1-\gamma) \frac{\partial^2 \psi}{\partial x^2} - \frac{1}{2} \left(\frac{\partial \psi}{\partial x} \right)^2 \right] \frac{1}{U} dx$$

$$\boxed{C_D = \frac{1}{M^2} D(M^2 \frac{f}{b})}$$

$$\boxed{C_L = \frac{1}{M^2} L(M^2 \frac{f}{b})}$$

Checks with the Linear Aircraft theory!

$$C_D \sim \frac{1}{M^2}$$

Quasi-symmetric flows

$$+ \frac{1}{2} \rho U^2 \frac{\partial^2 \psi}{\partial x^2} + \frac{1}{2} \rho U^2 \left(\frac{\partial \psi}{\partial x} \right)^2 + \frac{1}{2} \rho U^2 \left(\frac{\partial \psi}{\partial y} \right)^2$$

$$+ \left[(1-\gamma) \frac{\partial^2 \psi}{\partial x^2} - \frac{1}{2} \left(\frac{\partial \psi}{\partial x} \right)^2 \right] \frac{1}{U} \frac{\partial \psi}{\partial y}$$

Boundary conditions, at ∞ , $\psi = 0$

$$\text{At } y=0, \quad \left(\frac{\partial \psi}{\partial y} \right)_{y=0} = a' M^2 f(\xi) \frac{1}{b} = 0$$

$$\frac{1}{2} \rho U^2 \frac{\partial^2 \psi}{\partial x^2} + \frac{1}{2} \rho U^2 \left(\frac{\partial \psi}{\partial x} \right)^2 + \frac{1}{2} \rho U^2 \left(\frac{\partial \psi}{\partial y} \right)^2$$

$$= \frac{1}{2} \rho U^2 \frac{\partial^2 \psi}{\partial x^2} + \left[M^2 f(\xi) \right]^2 \frac{\partial \psi}{\partial y}$$

In the first part section, the general theory, it is well known that in the second section, the theory will be applied to the case of compressible flow over an airfoil.

Section (1)

If p is the pressure and ρ is the density of gas, the adiabatic relation process is expressed as a

function of p and ρ as shown in fig. 1. The equation of the tangent at this point can be written as

$$p_1 - p = C(\rho_1 - \rho) = C(\rho_1^{-1} - \rho^{-1}) \quad (31)$$

where ρ is the density of the gas. Now the slope of the tangent at this point is given by

$$\frac{dp}{d\rho} = -\frac{1}{\rho^2}$$

Therefore $C = -a^2 \rho^2$ ~~(32)~~

Hence the approximate p - ρ relation near p_1, ρ_1 can be written as

$$p_1 - p = a_1^2 \rho_1^2 \left(\frac{1}{\rho} - \frac{1}{\rho_1} \right) \quad (32)$$

1) From the super derivative of ϕ ~~we get~~ ϕ 5)
 and the following relation:

From the supersymmetry invariance theorem the following
 relation is obtained:

where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (1)
 and $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (2)
 and $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (3)

where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (4)

where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (5)
 integrate; the following relation is obtained

$$\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$$

Now if $\omega_3 = 0$, $\omega_2 = \omega$, $\phi_3 = \phi_0$ and $\phi_2 = \phi$, then

$$\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$$

where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (6)
 and $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (7)
 where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (8)

$$\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$$

where $\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$ (9)

$$\frac{1}{2} \omega^2 = \frac{1}{2} \dot{\phi}^2 - \frac{1}{2} \dot{\phi}^2$$

HH

[illegible]

[Faint handwritten notes, possibly bleed-through from the reverse side.]

(4.1) and #3.8) the upper limit is found to be

$$\left(\frac{u}{w}\right)_{\max} = \frac{1}{\frac{u}{w}} \sqrt{\frac{f}{f_0} \left(\frac{f}{f_0} + 1\right)^2 \left(\frac{f}{f_0} - 1\right)}$$

by putting $i^2 = f \frac{f}{f_0}$ the above equation reduces to

$$\left(\frac{u}{w}\right)_{\max} = \frac{1}{\frac{u}{w}} \sqrt{\frac{f}{f_0} \left(\frac{f}{f_0} + 1\right)^2 \left(\frac{f}{f_0} - 1\right)}$$

The values of $\left(\frac{u}{w}\right)_{\max}$ for different values of f/f_0 are shown in Table 3.1

f/f_0	$\left(\frac{u}{w}\right)_{\max}$	$\left(\frac{u}{w}\right)_{\max}$
0	0	0
0.2	0.9	0.75
0.4	1.2	1.0
0.6	1.4	1.2
0.8	1.6	1.4
1.0	1.8	1.6

It is clear from the above that for most practical applications of this theory, f will be small, and the above values are due to large deviation from the true values. Hence at higher values of f/f_0 , the values of $\left(\frac{u}{w}\right)_{\max}$ will be higher than the values given in the above table.

$$w \quad \left| \frac{S}{S_0} \right| = \sqrt{1 - \frac{\omega^2}{a^2}} \quad (37) \quad (6)$$

Furthermore, from Eq. (36), $S_1^2 a_1^2 = S_0^2 a_0^2$, thus Eq. (37) can also be written as

$$\left| \frac{S}{S_0} \right| = \frac{a_0}{a_1} \quad (38)$$

Now if the flow is irrotational, ~~so~~ there exists a velocity potential Φ such that

$$\frac{\partial \Phi}{\partial x} = u, \quad \frac{\partial \Phi}{\partial y} = v \quad (39)$$

where u & v components of the velocity w

at the point (x, y)

"

"

Now if the angle of inclination of the velocity w to the x -axis is β

$$d\Phi = w \cos \beta dx + w \sin \beta dy \quad (311)$$

where w is the velocity

$$\left. \begin{aligned} dx &= \frac{\cos \beta}{w} d\Phi - \frac{\sin \beta}{w} \frac{S_0}{S} d\psi_0 \\ dy &= \frac{\sin \beta}{w} d\Phi + \frac{\cos \beta}{w} \frac{S_0}{S} d\psi_0 \end{aligned} \right\} \quad (312)$$

is 1:1 correspondence between the ~~space~~ plane (1) and the hodoplane is one to one, or mathematically
 $\frac{\partial \phi}{\partial \beta} \neq 0$ we can express ϕ as a function of β .
 Therefore we can ~~write~~ $\phi = \phi(\beta)$ and $d\phi = \phi' d\beta$

$$\begin{aligned} d\phi &= \phi'_w dw + \phi'_\beta d\beta \\ d\psi &= \psi'_w dw + \psi'_\beta d\beta \end{aligned} \quad (3/3)$$

where ϕ' indicates the derivative of ϕ with respect to the variables with respect to which ϕ is a function. In our differentials the substitutions $\phi = \phi(\beta)$ and $d\phi = \phi' d\beta$ the following relations are obtained

$$d\phi = \left(\frac{\cos \beta}{u} \phi'_u - \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) dw + \left(\frac{\cos \beta}{u} \phi'_u + \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) d\beta$$

$$\text{or } \left(\frac{\cos \beta}{u} \phi'_u - \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) dw + \left(\frac{\cos \beta}{u} \phi'_u + \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) d\beta = \phi'_w dw + \phi'_\beta d\beta$$

Since the left hand side of (3/4) is an exact differential we can apply the corresponding conditions

$$\frac{\partial}{\partial \beta} \left(\frac{\cos \beta}{u} \phi'_u - \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) = \frac{\partial}{\partial w} \left(\frac{\cos \beta}{u} \phi'_u + \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right)$$

$$\frac{\partial}{\partial w} \left(\frac{\cos \beta}{u} \phi'_u - \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right) = \frac{\partial}{\partial \beta} \left(\frac{\cos \beta}{u} \phi'_u + \frac{\sin \beta}{u} \frac{1}{c} \phi'_c \right)$$

arrange at the substitution and canceling identical ϕ terms on both hand and right hand side.

$$\begin{aligned} \frac{\cos \beta}{\omega} \phi_{\omega} - \frac{\sin \beta}{\omega} \frac{S}{\omega} \psi_{\omega} &= \frac{\cos \beta}{\omega} \phi_{\beta} + \frac{\sin \beta}{\omega} \frac{S}{\omega} \psi_{\beta} \\ \frac{\sin \beta}{\omega} \phi_{\omega} - \frac{\cos \beta}{\omega} \frac{S}{\omega} \psi_{\omega} &= \frac{\sin \beta}{\omega} \phi_{\beta} - \frac{\cos \beta}{\omega} \frac{S}{\omega} \psi_{\beta} \end{aligned} \quad (3.16)$$

Using Eq. (3.7), Eq. (3.16) becomes

$$\begin{aligned} -\frac{\sin \beta}{\omega} \phi_{\omega} - \frac{\cos \beta}{\omega} \frac{S}{\omega} \psi_{\omega} &= \frac{\sin \beta}{\omega} \phi_{\beta} + \frac{\cos \beta}{\omega} \frac{S}{\omega} \psi_{\beta} \\ \frac{\cos \beta}{\omega} \phi_{\omega} - \frac{\sin \beta}{\omega} \frac{S}{\omega} \psi_{\omega} &= -\frac{\sin \beta}{\omega} \phi_{\beta} - \frac{\cos \beta}{\omega} \frac{S}{\omega} \psi_{\beta} \end{aligned} \quad (3.17)$$

As we can see from the above equations, the terms involving ϕ and ψ are not separated. To separate them, we need to introduce a new variable χ defined as follows:

$$\begin{aligned} \chi &= \phi + \frac{S}{\omega} \psi \\ \chi &= \phi - \frac{S}{\omega} \psi \end{aligned}$$

By using the above definition, a new variable is defined as introduced. Let's define

$$\chi = \phi + \frac{S}{\omega} \psi \quad (3.18)$$

to iteration

Let $u = x + iy$ and $v = x - iy$ (3.21)

$u = W \sin \beta$ are used as independent variables, then one

$$\frac{\partial}{\partial u} = \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} = \frac{1}{2} \left(\frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right) + \frac{i}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right)$$

$$\frac{\partial}{\partial v} = \frac{\partial}{\partial x} - i \frac{\partial}{\partial y} = \frac{1}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) - \frac{i}{2} \left(\frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right)$$

Hence $\frac{\partial}{\partial u} = \frac{1}{2} \left(\frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right) + \frac{i}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right)$ (3.22)

$$\frac{\partial}{\partial v} = \frac{1}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) - \frac{i}{2} \left(\frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right)$$

$$= \cos \beta \frac{\partial \psi}{\partial u} + \sin \beta \frac{\partial \psi}{\partial v}$$

These equations are satisfied by

$$\frac{\partial}{\partial u} = \frac{1}{2} \left(\frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right) + \frac{i}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right)$$

Let us now show that ψ is a function of u and v .

Therefore the potential $\psi = \psi(u, v)$

a function of u and v .

$$\phi + i\psi = F(u - iv) = F(\bar{w})$$

$$\text{then } \phi - i\psi = \bar{F}(u + iv) = \bar{F}(w) \quad \left. \vphantom{\begin{matrix} \phi + i\psi = F(u - iv) = F(\bar{w}) \\ \phi - i\psi = \bar{F}(u + iv) = \bar{F}(w) \end{matrix}} \right\} (3.26)$$

It is to be noted from hodograph plane back to

then it shows the ^{for the} $\psi = \psi(u, v)$

By using Eqs (3.22) and (3.23)

then as

$$dx = \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}}$$

$$dy = \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}} + \frac{1}{2} \frac{d\bar{F}}{d\bar{F}}$$

where $\bar{F}^2 = (x^2 + y^2)$. Here equation (326) can be converted into one equation by means of Eq. (326). Thus

$$dz = dx + idy = \frac{dF}{W} - \frac{W \cdot d\bar{F}}{4a_0^2} \quad (327)$$

It is found that the above equation is not exact. To make it exact, we choose the potential F such that $F = 0$ at the origin and the reaction potential \bar{F} is the same as F at the origin. In the above case,

$$F = G(s) = 0$$

where s is the arc length of the curve C starting from the origin. Then $F = 0$ at the origin, and $\bar{F} = 0$ at the origin.

(II) Now let $F = W_1 G(s)$. Here W_1 is the constant "weight" of the curve C . Then $F = 0$ at the origin, and $\bar{F} = 0$ at the origin.

$$F = W_1 G(s) = 0$$

(III) Using the above value of F , Eq. (327) can be written as

$$dz = ds - \frac{1}{4} \left(\frac{W_1}{a_0} \right)^2 \left(\frac{d\bar{F}}{ds} \right)^2 ds \quad \text{Next}$$

The factor $\frac{1}{\gamma}$ before the integral depends upon the Mach's number of the undisturbed flow only. By using

Thus by putting $w = w_1$, one obtains

$$\frac{w_1}{W_1} = \frac{1}{1 - \frac{1}{4} \left(\frac{W_1}{a_0} \right)^2}$$

Thus $\frac{w}{W} = 1 + \frac{1}{4} \frac{W_1^2}{a_0^2} \cdot \frac{\frac{W_1}{W_1}}{1 - \frac{1}{4} \left(\frac{W_1}{a_0} \right)^2 \left(\frac{W_1}{W_1} \right)^2}$ (3.29)

Using Eqs. (3.28) and (3.29) the ratio $\frac{w}{W}$ can be calculated easily.

17 To determine the pressure acting on the surface of the body one has to use Eq. (3.2) with some manipulation the following relation is obtained

$$\frac{L}{a^2} = \frac{L}{a^2} \left(1 + \frac{S_0}{S} \right) \quad (3.30)$$

$$\frac{L}{a} = \frac{L}{a} \left(1 + \frac{S_0}{S} \right) \quad (3.31)$$

where put $\frac{S_0}{S} = \sqrt{1 + \left(\frac{w}{W_1} \right)^2 \left(\frac{W_1}{a_0} \right)^2}$

$$\frac{L}{a} = \frac{L}{a} \left(1 + \sqrt{1 + \left(\frac{w}{W_1} \right)^2 \left(\frac{W_1}{a_0} \right)^2} \right) \quad (3.32)$$

Therefore $\frac{L}{a} = \frac{L}{a} \left(1 + \sqrt{1 + \left(\frac{w}{W_1} \right)^2 \left(\frac{W_1}{a_0} \right)^2} \right) \quad (3.32)$

Section II

(14)

In the next section the general theory developed in Section I, is applied to the special case of flow over a symmetrical airfoil at zero angle of attack. The complex potential in the circle-plane (see Fig 3.2) is known to be

$$w, \left\{ (\mu - b) + \frac{a^2}{\mu - b} \right\} \quad (3.33)$$

where a = radius of the unit circle b = secant of the angle of attack. The relation between the airfoil plane and circle plane is the well known Joukowski transformation

$$z = \mu + \frac{a^2}{\mu} \quad (3.34)$$

if the radius of the transforming circle is unity,

the starting point of the calculation is the function to be found $\frac{d\bar{w}}{dz} = u dz$

$$u dz = \frac{dz}{dz} \frac{d\bar{w}}{d\mu} d\mu = \left(\frac{d\bar{w}}{d\mu} \right) \frac{dz}{d\mu} d\mu$$

$$\text{Therefore } \frac{d\bar{w}}{dz} = \frac{1}{2} \left(\frac{1}{1 + \frac{1}{\mu}} \right) \left(\frac{1}{1 + \frac{1}{\mu}} \right) = \frac{1}{2} \left(\frac{\mu}{\mu + 1} \right)$$

Thus the correction term in Eqs (3.28) is

$$\frac{1}{2} \left(\frac{\mu}{\mu + 1} \right) d\bar{w} = \frac{1}{2} \left(\frac{1}{1 + \frac{1}{\mu}} \right) \left(\frac{1}{1 + \frac{1}{\mu}} \right) d\bar{w} \quad (3.35)$$

$$\text{where } I = \int_0^{\infty} \left(\frac{a^2 \mu^2}{\mu^2 + b^2} + \frac{a^4}{\mu^2 + b^2} \right) d\mu$$

(15)

$$I_1 = \int_0^{\infty} \left(\frac{a^2 \mu^2}{\mu^2 + b^2} + \frac{a^4}{\mu^2 + b^2} \right) \frac{d\mu}{\mu + 1}$$

$$I_2 = \int_0^{\infty} \left(\frac{a^2 \mu^2}{\mu^2 + b^2} + \frac{a^4}{\mu^2 + b^2} \right) \frac{d\mu}{\mu + 1}$$

These integrals can be easily computed & simplified noting that $a = b = 1$, $\mu = e^{i\theta}$ and $d\mu = i e^{i\theta} d\theta$

$$I_1 = a \left\{ e^{i\theta} + 2e^{-i\theta} + \frac{1}{3}e^{-i3\theta} \right\}$$

(16)

$$I_2 = \frac{1}{2} \left\{ \frac{1}{b} - e^{i\theta} + \frac{1}{2}e^{-i\theta} + \frac{1}{3}e^{-i3\theta} + \log(ae^{i\theta}) \right\}$$

$$= \left\{ \frac{1}{2} \log(ae^{i\theta}) + \frac{1}{2} + \frac{1}{2}(2-1)\log(ae^{i\theta}) \right.$$

$$\left. + \frac{1}{2}(1-1^2)e^{-i\theta} + \frac{1}{2}e^{-i2\theta} - \frac{1}{3}e^{-i3\theta} \right\}$$

Separate the real and imaginary parts and add

$$\text{Re}(I_1 + I_2 - I_3) = a \left(3\cos\theta - \frac{1}{3}\cos 3\theta \right)$$

$$+ \frac{1}{2} \log(ae^{i\theta}) + \frac{1}{2} + \frac{1}{2}(2-1)\log(ae^{i\theta})$$

$$+ \frac{1}{2}(1-1^2)\cos 2\theta + \frac{1}{3}(1+1)\cos 3\theta \}$$

(17)

$$\text{Im}(I_1 + I_2 - I_3) = a \left(-\sin\theta + \frac{1}{3}\sin 3\theta \right)$$

$$+ \frac{1}{2} \log(ae^{i\theta}) + \frac{1}{2} + \frac{1}{2}(2-1)\log(ae^{i\theta})$$

$$- (1-1^2)^2 \tan^{-1} \frac{\sin\theta}{\cos\theta + \frac{1}{2}} + (1-1^2)^2 \theta \}$$

is neglected this is allowable because the quantity ϵ is a second order quantity.

The determination of ϵ can be carried out by using the method developed by van der Waals and Telford.

For some technical reasons the van der Waals method is somewhat modified.

We now choose two surfaces like C_1 and C_2 one of which is a sphere and the other is the surface of a cylinder.

We now apply the homography transformation to this figure then the transformed figure will be a sphere and a cylinder.

We choose the sphere as a new circular shape, in which case the transformed surface C_2 will appear like C_2' in the figure.

The difference between C_2 and C_2' is just ϵ and is equal to ϵ but ϵ is small so we let $\epsilon = 0$.

Then we have $C_2' = R C_2^0$ where R is a constant.

Then $R = [1 + \epsilon]$ 318

where ϵ is the small quantity which we are neglecting.

The figure which establishes the conformal transformation.

The figure shows the transformation into a circle of radius R and the figure shows the transformation into a circle of radius R .

$$\zeta_1 = \zeta_2 [1 + f(\zeta_2)] \quad (18) \quad (3.39)$$

where ζ_1 & ζ_2 have their origin at the center 0 and the absolute value $|f(\zeta_2)|$ is again small compared with 1. Then it is shown that (Ref. 7) that

$$g(0) + \text{Re.}[f(\zeta_2)] = 0. \quad (3.40)$$

To in order to calculate $f(\zeta_2)$ we develop the function $g(0)$ in a Fourier series.

$$g(0) = \sum_{n=0}^{\infty} a_n \cos n\theta \quad (3.41)$$

Here only cosine terms appear because the profile is symmetrical about the chord. On the other hand the complex function $f(\zeta_2)$ has the form for $|\zeta_2| \gg 1$

$$f(\zeta_2) = \sum_{n=0}^{\infty} \frac{c_n}{\zeta_2^n} \quad (3.42)$$

In fact $\zeta_2 \approx 1$ then (3.40) is satisfied by

$$c_n = -a_n$$

Thus
$$f(\zeta_2) = -\sum_{n=0}^{\infty} \frac{a_n}{\zeta_2^n} \quad (3.43)$$

It can be easily seen that the velocity ~~at the~~ around the airfoil is proportional to the circulation Γ as

$$w = w_\infty \left| \frac{d\zeta_1}{d\zeta_2} \right| \quad (3.44)$$

where w_∞ is the velocity around the Joukowski airfoil

obtained by of Black Ref 3) ~~The differential~~ $\frac{p-p_0}{\rho u^2} = \dots$ (21)
~~which is the same as the~~ The values of $\frac{p-p_0}{\rho u^2}$ at \dots
 which a ~~solid~~ ^{ideal} gas will attain a velocity ~~of~~ equal
 to the local ~~sound~~ ^{velocity} \dots it is thus ~~seen~~ ^{clear}
 that the effect of compressibility on pressure
 distribution is appreciable, even ~~at~~ ^{at} speed when
 no where the local ~~sound~~ ^{velocity} is \dots
 One should however bear in mind that the effect
 in the free neighborhood of the ~~airfoil~~ ^{airfoil} will ~~not~~ ^{probably}
 be so marked as with the pressure distribution.
 because ~~the~~ ^{the} ~~free~~ ^{free} ~~is~~ ^{is} the algebraic difference of pressure
 free ~~side~~ ^{side} ~~of~~ ^{of} the ~~section~~ ^{section}

Thus the present method gives a ~~definite~~ hyper value (2)
However the flow over a cylinder is rather ~~inaccurate~~
case. Because the difference ^{between} of ~~interests~~ is the sheet
to be calculated and the undisturbed velocity is
large and this ~~undisturbed~~ ^{is approximately} at α ~~is~~ α
1.1, ~~is moving into the tangent to the~~

Handwritten title

The first part of the paper is devoted to a review of the literature on the subject of the influence of the environment on the development of the individual. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the second part of the paper, the author discusses the influence of the environment on the development of the individual in the field of psychology. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the third part of the paper, the author discusses the influence of the environment on the development of the individual in the field of sociology. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the fourth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of education. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the fifth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of medicine. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the sixth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of law. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the seventh part of the paper, the author discusses the influence of the environment on the development of the individual in the field of politics. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the eighth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of economics. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the ninth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of history. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

In the tenth part of the paper, the author discusses the influence of the environment on the development of the individual in the field of philosophy. It is found that the influence of the environment is very great, and that it is not only the physical environment, but also the social and cultural environment, which have a profound effect on the individual.

it is more likely to give way under stress (b)
than at the

The true structure of the material has a great
effect on its behavior ~~and~~ it is not the same
in all cases. It is also affected by the direction
of the stress. The type of stress is also
important. At first, it is a simple
tension. It is then a compression. It is then a
shear. It is then a bending. It is then a
torsion. It is then a vibration. It is then a
rotation. It is then a translation. It is then a
combination of all these.

It is not enough to know the direction of the stress.
It is also important to know the magnitude of the stress.
The magnitude of the stress is determined by the
force applied to the material. It is also determined by
the area of the material. It is also determined by the
time of application of the stress.

It is also important to know the duration of the stress.
It is not enough to know the direction and magnitude of the stress.
It is also important to know the duration of the stress. In the literature,
it is often stated that the duration of the stress is important.
It is not enough to know the direction and magnitude of the stress.
It is also important to know the duration of the stress. It is also important to know the frequency of the stress.
It is also important to know the amplitude of the stress. It is also important to know the phase of the stress.

Isotropic shell

The buckling of cylindrical shell is of the same type
as that of isotropic plate the buckling load
is given by the same formula as for the isotropic plate
with the same boundary conditions.

It is the same as that of isotropic plate
with the same boundary conditions as for the isotropic plate
with the same boundary conditions.

The buckling load is the same as for the isotropic plate
with the same boundary conditions.

If the shell is of the same type as that of the isotropic plate
with the same boundary conditions, the buckling load is the same
as for the isotropic plate with the same boundary conditions.
The buckling load is the same as for the isotropic plate
with the same boundary conditions. W. Flüge (4) W. Flüge
in the last part of his paper tried to explain the
discrepancy by assuming the end conditions more
carefully, but it is not possible to do so
with the same boundary conditions. The buckling load
is the same as for the isotropic plate with the same
boundary conditions. The buckling load is the same
as for the isotropic plate with the same boundary conditions.
The buckling load is the same as for the isotropic plate
with the same boundary conditions.

The first method is the most common, and is the one which is generally used in the laboratory. It consists in placing a small quantity of the substance to be examined in a test tube, and adding a few drops of water. The mixture is then heated, and the gas evolved is passed through a solution of lime water. If the gas is carbon dioxide, the lime water will become turbid. This method is very simple and easy to perform, and is suitable for the detection of carbon dioxide in most cases. However, it is not very accurate, and it is not possible to measure the amount of gas evolved. The second method is more accurate, and it is possible to measure the amount of gas evolved. It consists in placing a small quantity of the substance to be examined in a test tube, and adding a few drops of water. The mixture is then heated, and the gas evolved is passed through a solution of lime water. If the gas is carbon dioxide, the lime water will become turbid. This method is very simple and easy to perform, and is suitable for the detection of carbon dioxide in most cases. strain energy method is studied by a sequence of (7)
The first is the necessary condition the
linear bending in case of small deflection theory
is ~~linear~~ ~~linear~~ so that condition of
a stationary strain energy is sufficient
then the condition is sufficient. The solution is
the same as the linear case because the strain energy is
a quadratic function of the deflection. In the case of
non-linear deflections, the strain energy is not a quadratic
function of the deflection. In this case the condition of
stationary strain energy is necessary but not sufficient.
The condition of stationary strain energy is not sufficient
in the case of large deflections. In this case the
condition of stationary strain energy is not sufficient.
In terms of the extremum condition is not linear.
Therefore, the condition is not sufficient for
each load condition. To decide which is
the true minimum, one has to use the second variation
method. One must use the method of the second variation
to decide which is the true minimum.

The Buckling of Thin Cylindrical Shells under Axial Compression

1

10/12

THE BUCKLING OF CYLINDRICAL SHELLS UNDER

Th. von Karman and Hsue-shen Tsien

California Institute of Technology

In two previous papers (Ref.1 and Ref.2), the authors have discussed in detail the inadequacy of the classical theory of thin shells in explaining the buckling phenomenon of ~~both the~~ cylindrical ~~shells~~ and ~~the~~ spherical shells. It was shown that not only the calculated buckling load is 4 to 5 times higher than that experimentally observed, but the buckling wave pattern found is also different from that predicted. It was pointed out, furthermore, that the different explanations for this discrepancy advanced by L.H. Donnell⁽¹⁾ and N. Flügge⁽²⁾ are untenable when certain conclusions drawn from these explanations are compared with the experimental facts. The authors are then led by ~~both the~~ theoretical investigation on spherical shells (Ref.1) ~~and~~ a model experiment (Ref.2) on thin columns ~~supported~~ with non-linear elastic support to the belief that the buckling phenomenon of curved shells can only be explained by means of ~~the~~ non-linear large deflection theory. ~~from the case in which~~ ~~the load is applied to the shell~~ to keep the shell in equilibrium ~~the load is applied to the shell~~ buckle. This characteristic of dropping load shows, ~~first~~ that the load drops on the shell buckling has started, and thus explains the observed rapidity

of the buckling process. Furthermore, this characteristic also brings in the possibility of a decrease in ^{the} buckling load when there are slight imperfections in the test specimen and when there are vibrations during the testing process.

In this paper, the authors will show by means of an approximate calculation the dropping load characteristic ~~increase~~ of a uniform, thin cylindrical shell under axial compression. Consequently, they hope that they have thus offered an acceptable explanation of the observed facts.

Stresses in the Median Surface and the
Expression for the Total Energy of the
System

If u , v , and w ^(2, 1) are the displacement of a point on the median surface of the shell in the axial, x -direction, the circumferential, y -direction, and the radial direction, then the unit strains in the x and y directions, ϵ_x , ϵ_y and the unit shear γ_{xy} at a point in the median surface can be expressed in the following form, including terms

of the second order:

$$\begin{aligned}\epsilon_x &= \frac{\partial u}{\partial x} + \frac{1}{2} \left(\frac{\partial v}{\partial x} \right)^2 \\ \epsilon_y &= \frac{\partial v}{\partial y} + \frac{1}{2} \left(\frac{\partial u}{\partial y} \right)^2 - \frac{w}{R} \\ \gamma_{xy} &= \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} + \left(\frac{\partial u}{\partial x} \right) \left(\frac{\partial v}{\partial y} \right)\end{aligned} \quad (1)$$

where R is the radius of the undeformed median surface of the shell. The strains ϵ_x , ϵ_y and γ_{xy} in the median surface of the shell are, however, related to each other by the ^{following} ~~equation~~ ^{equations}

$$\epsilon = \frac{E}{1-\nu^2} (\epsilon_x + \nu \epsilon_y)$$

$$\tau_{xy} = \epsilon_y + \nu \epsilon_x$$

where $\epsilon_x, \epsilon_y, \tau_{xy}$ are the components of the strain tensor and ν is the Poisson's ratio. The stress components $\sigma_x, \sigma_y, \tau_{xy}$ are related to the strain components by the constitutive equations of the material.

$$\begin{aligned} \sigma_x &= \frac{E}{1-\nu^2} (\epsilon_x + \nu \epsilon_y) \\ \sigma_y &= \frac{E}{1-\nu^2} (\nu \epsilon_x + \epsilon_y) \\ \tau_{xy} &= G \gamma_{xy} \end{aligned}$$

expressed by the following equations in case of thin shells:

$$\left. \begin{aligned} \frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{xy}}{\partial y} &= 0 \\ \frac{\partial \tau_{xy}}{\partial x} + \frac{\partial \sigma_y}{\partial y} &= 0 \end{aligned} \right\} (4)$$

introducing the well-known Airy stress function, F , defined by the relations

$$\sigma_x = \frac{\partial^2 F}{\partial y^2}, \quad \tau_{xy} = -\frac{\partial^2 F}{\partial x \partial y}, \quad \sigma_y = \frac{\partial^2 F}{\partial x^2}$$

Eliminating the variables u and v between Eqs. (3) and (5)

the relation between the Airy stress function, F and the radial displacement u is obtained;

$$\frac{\partial^4 F}{\partial x^4} + \frac{\partial^4 F}{\partial x^2 \partial y^2} + \frac{\partial^4 F}{\partial y^4} = \frac{1}{r^2} \frac{\partial^2 u}{\partial r^2}$$

This equation is very similar to the large deflection equation for flat plate derived by the senior author. (Ref 5)

L.H. Donnell (Ref; 3) first obtained this equation in its present form. With a given form of the radial ^{component of the displacement} deflection ~~equation~~,

Eq. (6) gives the induced stresses in the median surface of

the shell. ~~These stresses will be maximum at the ends of the shell~~ ^{For a long shell, the first two terms in the stress equation are negligible compared to the third term, and the following equation}

$$\sigma = \frac{E}{1-\nu^2} \int_0^a \int_0^b (x^2 + y^2) - 2(1+\nu) (x^2 y + T_{xy}^2) dx dy \quad (7)$$

where a and b are the half wave lengths in the axial and the circumferential direction respectively.

It is necessary first to find the expressions for the change of

~~radii~~ of curvatures and ^{the} unit twist of the median surface.

In this case the following simplified expressions ^{will be} used:

$$\chi_x = \frac{\partial^2 w}{\partial x^2}, \quad \chi_y = \frac{\partial^2 w}{\partial y^2}, \quad \chi_{xy} = \frac{\partial^2 w}{\partial x \partial y} \quad (8)$$

In Eq. (8), certain additional terms in χ_y and χ_{xy} involving ν are neglected. It was shown by L.H. Donnell (Ref. 6)

that these terms ~~have a factor~~ differ from the terms retained

in Eq. (8) by a factor $1/n^2$, where n is the number of waves in

the circumferential direction. For thin cylindrical shells,

the value of n is ~~usually~~ around 10; therefore the neglect

is justified. With these expressions for the change of

the curvatures and ^{the unit} twist of the median surface, the bending

γ for one complete wave panel
 can be obtained as

$$W_1 = \frac{1}{2} \int_0^{2\pi} \int_0^{2\pi} \left[\frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2 + \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{1}{2} \left(\frac{\partial w}{\partial z} \right)^2 \right] dx dy dz$$

The lowering of the potential of the applied force on the end of the cylindrical shell can be calculated as the product of the change in length of the shell and the applied force. This can be expressed as follows:

$$W_2 = \frac{1}{2} \int_0^{2\pi} \int_0^{2\pi} \left[\frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2 + \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{1}{2} \left(\frac{\partial w}{\partial z} \right)^2 \right] dx dy dz$$

The equilibrium condition of the shell is obtained by equating the first variation of the sum of energies, W_1, W_2 and W_3 to zero. In the following calculation, the Rayleigh-Ritz method or the energy method will be used by assuming a plausible form for the function w .

Calculation of the Total Energy

To obtain a plausible form for w , one has to resort to the following consideration. It is known that for large values of the wave amplitude, the waves are so-called diamond shaped. This particular wave shape can be approximately expressed by

$$w = \cos^2 \left(\frac{m'x + ny}{2R} \right) \cos^2 \left(\frac{m'x - ny}{2R} \right) \quad (11)$$

where the squares are introduced to account for the fact that the shell has a definite preference to buckle inward. Eq. (11)

can be rewritten as

$$\frac{1}{r} = \frac{1}{R} + \frac{r_1}{R^2} + \frac{r_2}{R^3} + \frac{r_3}{R^4} + \frac{r_4}{R^5} + \frac{r_5}{R^6}$$

On the other hand, the classical theory which is correct for infinitesimal values of the wave amplitude, requires the waves to be of the form

$$\cos \frac{\pi x}{R} \cos \frac{\pi y}{R} \quad (13)$$

In order to satisfy this requirement, the wave form assumed in the following calculations is of the

$$f_0 + f_1 + f_2 + f_3 + f_4 + f_5 + f_6 + f_7 + f_8 + f_9 + f_{10} + f_{11} + f_{12} + f_{13} + f_{14} + f_{15} + f_{16} + f_{17} + f_{18} + f_{19} + f_{20} + f_{21} + f_{22} + f_{23} + f_{24} + f_{25} + f_{26} + f_{27} + f_{28} + f_{29} + f_{30} + f_{31} + f_{32} + f_{33} + f_{34} + f_{35} + f_{36} + f_{37} + f_{38} + f_{39} + f_{40} + f_{41} + f_{42} + f_{43} + f_{44} + f_{45} + f_{46} + f_{47} + f_{48} + f_{49} + f_{50} + f_{51} + f_{52} + f_{53} + f_{54} + f_{55} + f_{56} + f_{57} + f_{58} + f_{59} + f_{60} + f_{61} + f_{62} + f_{63} + f_{64} + f_{65} + f_{66} + f_{67} + f_{68} + f_{69} + f_{70} + f_{71} + f_{72} + f_{73} + f_{74} + f_{75} + f_{76} + f_{77} + f_{78} + f_{79} + f_{80} + f_{81} + f_{82} + f_{83} + f_{84} + f_{85} + f_{86} + f_{87} + f_{88} + f_{89} + f_{90} + f_{91} + f_{92} + f_{93} + f_{94} + f_{95} + f_{96} + f_{97} + f_{98} + f_{99}$$

where f_0 , f_1 , and f_2 are unknowns to be determined by conditions of minimum total energy of the system.

f_0 is introduced in order to allow the shell to expand

It is evident that no end effect can be taken into account;

the form of the end effect is not of the type of the main wave, and it is not possible to include it in the series (14) into Eq. (6), the differential

equation for the Airy stress function F is obtained:

$$\Delta^2 F = \frac{E \pi^2}{4 R^4} \left(\frac{1}{4} f_0 + \frac{1}{4} f_1 + \frac{1}{4} f_2 + \frac{1}{4} f_3 + \frac{1}{4} f_4 + \frac{1}{4} f_5 + \frac{1}{4} f_6 + \frac{1}{4} f_7 + \frac{1}{4} f_8 + \frac{1}{4} f_9 + \frac{1}{4} f_{10} + \frac{1}{4} f_{11} + \frac{1}{4} f_{12} + \frac{1}{4} f_{13} + \frac{1}{4} f_{14} + \frac{1}{4} f_{15} + \frac{1}{4} f_{16} + \frac{1}{4} f_{17} + \frac{1}{4} f_{18} + \frac{1}{4} f_{19} + \frac{1}{4} f_{20} + \frac{1}{4} f_{21} + \frac{1}{4} f_{22} + \frac{1}{4} f_{23} + \frac{1}{4} f_{24} + \frac{1}{4} f_{25} + \frac{1}{4} f_{26} + \frac{1}{4} f_{27} + \frac{1}{4} f_{28} + \frac{1}{4} f_{29} + \frac{1}{4} f_{30} + \frac{1}{4} f_{31} + \frac{1}{4} f_{32} + \frac{1}{4} f_{33} + \frac{1}{4} f_{34} + \frac{1}{4} f_{35} + \frac{1}{4} f_{36} + \frac{1}{4} f_{37} + \frac{1}{4} f_{38} + \frac{1}{4} f_{39} + \frac{1}{4} f_{40} + \frac{1}{4} f_{41} + \frac{1}{4} f_{42} + \frac{1}{4} f_{43} + \frac{1}{4} f_{44} + \frac{1}{4} f_{45} + \frac{1}{4} f_{46} + \frac{1}{4} f_{47} + \frac{1}{4} f_{48} + \frac{1}{4} f_{49} + \frac{1}{4} f_{50} + \frac{1}{4} f_{51} + \frac{1}{4} f_{52} + \frac{1}{4} f_{53} + \frac{1}{4} f_{54} + \frac{1}{4} f_{55} + \frac{1}{4} f_{56} + \frac{1}{4} f_{57} + \frac{1}{4} f_{58} + \frac{1}{4} f_{59} + \frac{1}{4} f_{60} + \frac{1}{4} f_{61} + \frac{1}{4} f_{62} + \frac{1}{4} f_{63} + \frac{1}{4} f_{64} + \frac{1}{4} f_{65} + \frac{1}{4} f_{66} + \frac{1}{4} f_{67} + \frac{1}{4} f_{68} + \frac{1}{4} f_{69} + \frac{1}{4} f_{70} + \frac{1}{4} f_{71} + \frac{1}{4} f_{72} + \frac{1}{4} f_{73} + \frac{1}{4} f_{74} + \frac{1}{4} f_{75} + \frac{1}{4} f_{76} + \frac{1}{4} f_{77} + \frac{1}{4} f_{78} + \frac{1}{4} f_{79} + \frac{1}{4} f_{80} + \frac{1}{4} f_{81} + \frac{1}{4} f_{82} + \frac{1}{4} f_{83} + \frac{1}{4} f_{84} + \frac{1}{4} f_{85} + \frac{1}{4} f_{86} + \frac{1}{4} f_{87} + \frac{1}{4} f_{88} + \frac{1}{4} f_{89} + \frac{1}{4} f_{90} + \frac{1}{4} f_{91} + \frac{1}{4} f_{92} + \frac{1}{4} f_{93} + \frac{1}{4} f_{94} + \frac{1}{4} f_{95} + \frac{1}{4} f_{96} + \frac{1}{4} f_{97} + \frac{1}{4} f_{98} + \frac{1}{4} f_{99} \right) + B \cos \frac{2\pi x}{R}$$

In the case of a shell of finite thickness, the end effect is not of the type of the main wave, and it is not possible to include it in the series (14) into Eq. (6), the differential

equation for the Airy stress function F is obtained:

where $\mu = \frac{1}{n}$, = the aspect ratio of the waves,

$$A = \frac{1}{8} f_1^2 n^2 - \left(\frac{1}{2} f_1 + f_2 \right)$$

$$B = \frac{1}{8} f_1^2 n^2$$

$$D = \frac{1}{4} \left(\frac{1}{2} f_1^2 + f_2^2 \right) n^2$$

$$E = \frac{1}{4} f_1 \left(\frac{1}{2} f_1^2 + f_2^2 \right) n^2$$

$$C = \frac{1}{2} f_1 \left(\frac{1}{2} f_1 + f_2 \right) n^2 - \frac{1}{2} f_1$$

$$F = \frac{1}{4} \left(f_1^2 + f_2^2 \right) n^2$$

The solution of this differential equation can be easily obtained as

$$f = - \left(\frac{1}{4} \mu^2 \frac{F}{R} + \frac{A}{16 \mu^4} \cos^2 \frac{2\pi y}{R} + \frac{B}{16} \cos \frac{2\pi y}{R} + \frac{C}{16} \cos^3 \frac{2\pi y}{R} + \frac{D}{16 \mu^2} \cos^2 \frac{2\pi y}{R} + \frac{E}{16 \mu^2} \cos \frac{2\pi y}{R} + \frac{F}{16 \mu^2} \right) + \frac{\alpha}{2} x^2 + \frac{\beta}{2} x^2$$

is obtained as can be written as

$$\begin{aligned} x &= \left(\mu^2 \frac{B}{4} \cos \frac{2\pi y}{R} + \frac{C}{\mu^4} \cos^3 \frac{2\pi y}{R} + \frac{D}{4 \mu^2} \cos^2 \frac{2\pi y}{R} + \frac{E}{4 \mu^2} \cos \frac{2\pi y}{R} + \frac{F}{4 \mu^2} \right) + \frac{\alpha}{2} x^2 + \frac{\beta}{2} x^2 \\ y &= \left(\frac{1}{4} \mu^2 \frac{F}{R} + \frac{A}{16 \mu^4} \cos^2 \frac{2\pi y}{R} + \frac{B}{16} \cos \frac{2\pi y}{R} + \frac{C}{16} \cos^3 \frac{2\pi y}{R} + \frac{D}{16 \mu^2} \cos^2 \frac{2\pi y}{R} + \frac{E}{16 \mu^2} \cos \frac{2\pi y}{R} + \frac{F}{16 \mu^2} \right) + \frac{\alpha}{2} x^2 + \frac{\beta}{2} x^2 \\ z &= \left(\frac{1}{4} \mu^2 \frac{F}{R} + \frac{A}{16 \mu^4} \cos^2 \frac{2\pi y}{R} + \frac{B}{16} \cos \frac{2\pi y}{R} + \frac{C}{16} \cos^3 \frac{2\pi y}{R} + \frac{D}{16 \mu^2} \cos^2 \frac{2\pi y}{R} + \frac{E}{16 \mu^2} \cos \frac{2\pi y}{R} + \frac{F}{16 \mu^2} \right) + \frac{\alpha}{2} x^2 + \frac{\beta}{2} x^2 \end{aligned}$$

In all experimental results, the data is usually expressed in term of the average compression stress $\bar{\sigma}$ in the axial direction. It can be easily seen from Eq.(18) that

$$\beta = -\bar{\sigma} \quad (19)$$

~~By solving~~ Using Eq.(3), ~~and substituting~~ for the following expressions for $\frac{\partial u}{\partial x}$ and $\frac{\partial v}{\partial y}$ can be obtained:

$$\frac{\partial u}{\partial x} = \frac{1}{E} (\bar{\sigma}_x - \nu \bar{\sigma}_y) - \frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2$$

$$\frac{\partial v}{\partial y} = \frac{1}{E} (\bar{\sigma}_y - \nu \bar{\sigma}_x) - \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{w}{R}$$

By substituting Eqs.(14) and (18) into Eq.(20), it is found that

$$\frac{\partial u}{\partial x} = \frac{1}{E} \left(\bar{\sigma}_x - \nu \bar{\sigma}_y \right) - \frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2 + \text{Cosine Term} \quad (21)$$

$$\frac{\partial v}{\partial y} = \frac{1}{E} \left(\bar{\sigma}_y - \nu \bar{\sigma}_x \right) - \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{w}{R}$$

Since ~~y-direction~~ ^{measured} is the circumferential direction, v must be a periodic function; therefore the constant term in $\frac{\partial v}{\partial y}$ must be ^{equal to} zero. Thus Or

$$\bar{\sigma}_y - \nu \bar{\sigma}_x = \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 - \frac{w}{R}$$

This is the condition ^{for the} determination of α .

Using Eqs. (18) and (22), the extensional energy of the shell is obtained as

$$\begin{aligned}
-\frac{W_1}{\frac{1}{2}Et ab} &= 4 \left[(1-\nu^2) \left(\frac{\tau}{E} \right)^2 + n^2 \left\{ \frac{3}{64} f_1^2 + \frac{1}{16} f_1 f_2 + \frac{1}{16} f_2^2 \right\}^2 \right. \\
&\quad \left. + \left(f_0 + \frac{1}{4} f_1 \right)^2 - 2n^2 \left\{ \frac{3}{64} f_1^2 + \frac{1}{16} f_1 f_2 + \frac{1}{16} f_2^2 \right\} \left(f_0 + \frac{1}{4} f_1 \right) \right] \\
&\quad + \left\{ \frac{A^2}{8} + \frac{B^2 \mu^4}{8} + \frac{\mu^4}{(1+\mu^2)} C^2 + \frac{\mu^4}{(4\mu^2+1)} D^2 + \frac{\mu^4}{\mu^2+0.1} E^2 \right. \\
&\quad \left. + \frac{\mu^4}{16(1+\mu^2)} F \right\}
\end{aligned}$$

Using Eqs. (9) and (18), the bending energy of the shell can be calculated as

$$\begin{aligned}
\frac{W_2}{\frac{1}{2}Et ab} &= \frac{1}{6(1-\nu^2)} \left(\frac{\tau}{E} \right)^2 \left\{ \frac{1}{8} (1+\mu^2) f_1^2 + \frac{1}{4} (1+\mu^4) \right. \\
&\quad \left. + (1+\mu^4) f_1 f_2 + (1+\mu^4) f_2^2 \right\} \quad (24)
\end{aligned}$$

The lowering in potential of the applied force can be obtained by means of Eqs. (10), (18), (21) and (22). The result is

$$\begin{aligned}
\frac{W_3}{\frac{1}{2}Et ab} &= - \left[2(1-\nu^2) \left(\frac{\tau}{E} \right)^2 + n^2 \left\{ \frac{3}{32} (\mu^2+1) f_1^2 \right. \right. \\
&\quad \left. \left. + \frac{1}{8} (\mu^2+1) f_1 f_2 + \frac{1}{8} (\mu^2+1) f_2^2 \right\} \frac{\tau}{E} - 2 \left(f_0 + \frac{1}{4} f_1 \right) \frac{\tau}{E} \right]
\end{aligned}$$

Relation between the Compression Stress and the Amplitude of Waves

To find the relation between the compression stress and the amplitude of the waves, the conditions which will make the sum of the energies W_1 , W_2 , and W_3 a minimum have to be obtained. It was found that the calculations can be simplified to a certain extent by first ~~not using the condition that~~

$$\frac{\partial}{\partial f_0} (W_1 + W_2 + W_3) = 0 \quad (26)$$

This condition will determine ^a ~~the~~ relation between f_0 and f_1 and f_2 , ~~which can be written as~~ ~~and the following expression is obtained~~

$$f_0 + \frac{1}{4} f_1^2 = \eta^2 \left[\frac{3}{64} f_1^2 + \frac{1}{16} f_1 f_2 + \frac{1}{16} f_2^2 \right] - \gamma \frac{\sigma}{E} \quad (27)$$

Substituting Eq. (27) into the expressions for W_1 , W_2 and W_3 as given by Eqs. (23), (24) and (25) and using Eq. (16), the total energy of the system is expressed finally in the following form:

$$\begin{aligned} \frac{W}{\gamma E \sigma} = & \frac{1}{2} f_1^2 + \frac{1}{2} f_2^2 + \frac{1}{2} f_1 f_2 \\ & + \frac{\mu^4}{2(\mu^2+1)^3} f_1^4 + \frac{\mu^4}{4(\mu^2+1)^2} f_2^4 + \frac{\mu^4}{16(\mu^2+1)^2} f_1^2 f_2^2 \\ & + \frac{\mu^4}{2(\mu^2+1)^3} f_1^3 f_2 + \frac{\mu^4}{4(\mu^2+1)^2} f_1^2 f_2^2 \} + \dots \end{aligned} \quad (28)$$

The equilibrium conditions are then obtained by differentiating the expression for total energy, Eq.(28), with respect to f_1 and f_2 , and then set these expressions equal to zero. The results can be written in a simpler form by introducing the following parameters

$$\begin{aligned} \beta &= f_2/f_1 \\ \gamma &= n^2 \frac{t}{R} \\ \xi &= f_1 \frac{R}{t} = \frac{f}{t} \end{aligned} \quad (29)$$

where f is the wave amplitude of the perturbed shell of the cylinder of radius R and thickness t .

Then the equilibrium conditions are

$$\frac{\partial E}{\partial f_1} = 0 \quad \text{and} \quad \frac{\partial E}{\partial f_2} = 0$$

Eliminating $\frac{\delta R}{E\ell}$ from the above equations, the following equation for ρ is obtained

$$A_3 \rho^3 + A_2 \rho^2 + A_1 \rho + A_0 = 0$$

where the coefficients are

$$A_3 = (\gamma \xi)^2 \left[\frac{3\mu^3}{(\mu^2 + 1)^2} + \frac{\mu^4}{(q\mu^2 + 1)^2} + \dots \right]$$

$$A_2$$

$$A_1$$

$$A_0$$

(32)

Thus with a given value of μ and γ , the coefficients for various values of the wave amplitude ξ can be first calculated by using the Eq.(32). Then Eq.(31) can be solved for different values of ρ corresponding to this particular value of μ and γ at various wave amplitude ξ . When the value of ρ is known, Eq.(30) can be used to calculate the corresponding value of the compression stress $\frac{\delta R}{E\ell}$. It is found, however, that the following expression for the compression stress which is obtained from Eq. (30) by

eliminating the third powers of ρ , is more suitable for numerical computation:

These calculation was carried out for two values of μ , $\mu = 1$ and $\mu = 0.5$, ~~the exact ratio of the wave lengths in circumferential direction and in axial direction.~~ ~~definitely~~ the ratio of the wave lengths in circumferential direction and in axial direction. These values of μ are 1 and 0.5. The former value was chosen, because the experiments indicates that at large wave amplitudes, the diamond waves have ^{almost} equal sides. The latter value of μ was chosen, because the experiments made by N. Nojima and S. Kanemitsu (Ref.2) show the occurrence of this type of waves. The results of these computations are shown in Fig.2 and Fig.3 where the compression stress is plotted against the wave amplitudes.

Thus the unit end shortening can be easily calculated by using the ~~values of μ and ν~~ ^{values of μ and ν} in Fig. 4 and 5. The compression stress is plotted against the unit end shortening, for ~~$\mu = 1$ and $\nu = 0.5$~~ ^{$\mu = 1$ and $\nu = 0.5$ respectively}. It is immediately clear from these two figures that if the buckling process follows the curves shown, then the shell starts at the point of starting ~~to compress~~ ^{with load}, ~~into means that the shell plate must~~ ^{it has a much lower compression stress}, ~~the buckling process is highly unstable before the start of the buckling process~~ ^{the buckling process is highly unstable before the start of the buckling process}, ~~without which a new wave has to move the end plate start~~ ^{without which a new wave has to move the end plate start}, ~~the buckling process is highly unstable before the start of the buckling process~~ ^{the buckling process is highly unstable before the start of the buckling process}. Therefore, the shell must first jump to the point P (Fig. 4 or 5) which has the same end shortening as the starting point of buckling process, but has a much lower compression stress. This jump definitely involves a release of elastic energy and thus explains the rapidity of buckling process observed in laboratory. ~~the buckling process is highly unstable before the start of the buckling process~~ ^{the buckling process is highly unstable before the start of the buckling process}.

However, it is still difficult to say ~~the shell will~~ ^{the shell will} jump ~~to a state with narrow waves, as shown by Fig. 5, or~~ ^{to a state with almost square waves, as shown by Fig. 4.} Superficially, one might conclude that narrow waves are ~~probable~~ ^{probable} because it gives a much ~~compression stress~~ ^{higher compression stress}, as can be seen by comparing Fig. 4 with Fig. 5. But at a given end shortening, ~~the true criterion~~ ^{the true criterion} ~~is that the elastic energy stored in~~ ^{is that the elastic energy stored in} the equilibrium position is that the elastic energy stored in

shell should be the lowest. An approximate calculation of the elastic energy of the shells shows that for values of $\lambda < 0.0121$, the occurrence of narrow waves is improbable, because the elastic energy is higher than that for square waves at same value of end shortening. However, for $\frac{ER}{\lambda}$ near 0.6, the elastic energy stored in the shell for narrow waves is comparable to that for the square waves at same values of λ . This indicates the possibility of the occurrence of narrow waves ~~even at the initial stages of buckling because the elastic energy is not very different from the value at the onset of buckling.~~ This is in agreement with the experimental findings of N.Nojima and S.Kanemitsu as reported in a previous paper by the present authors (Ref.2).

In any case it is ~~definite~~^{possible} that there are equilibrium positions of a buckled cylindrical shell which involve λ values $\lambda < 0.0121$ at the beginning of buckling. Take for instance, the square waves, ~~the~~^{in case of} the lowest compression stress is given by

$$\frac{\sigma}{E} = 0.194 \left(\frac{t}{R} \right) \quad (35)$$

This value corresponds closely to most of the experimental results ~~obtained by I.F.Dimitroff and I. ...~~^(Ref. 2) In the two previous papers (Ref.1 and Ref.2) the authors have pointed out that due to imperfections present in test specimen and vibrations in the surroundings, ~~it is~~^{it is} probable that the test buckling load will probably nearer to

the minimum load necessary to keep the shell in buckled

classical theory.

It thus seems that the experimental results are satisfactorily explained by the present approximate calculation. The results of the calculation, like the results of the experiment, show that the buckling phenomenon is a complex one and that the present calculation is still lacking in detail.

~~Experimental results~~

The Effect of the Elastic Characteristic of the Testing Machine on the Buckling Behavior

In the previous paragraphs, it is stated that the compression on the specimen is determined by the distance between the end plates which is in turn determined by the loading mechanism. However, in actual cases, there is always a certain amount of elasticity in the testing machine and thus the distance between the end plates is not only determined by the loading mechanism but also by the compression force ~~which~~ on the specimen. With the loading mechanism

will force the end plates apart and thus reduce the end shortening

a linear elastic behavior, the compression load is related to the end shortening by parallel straight lines ^{each} for constant values of, ~~any~~ number of turns of the loading crank of the testing machine. If the loading crank is held at a fixed position, then the compression load of the specimen must follow the straight line corresponding to this crank position.

In Fig.6, the load-end shortening curves of different characteristics are plotted on a system of straight lines representing the characteristics of the testing machine. It is evident that after the maximum, or initial buckling load is reached, the shell will jump to ^{new} equilibrium state involving much lower compression load. The new equilibrium state is determined by the slope of the load-end shortening curve. A curve A will give higher load than the curve B (Fig.6). ^{by first factor is} Secondly, the elastic character of the testing machine. A more elastic machine will give a set of characteristic straight lines having smaller slopes. Therefore, in case of Curve A, a more elastic machine will result in a higher load, while in case of curve B, a more elastic machine will result in a lower load. Therefore, the buckling behavior of a cylindrical shell is ^{not} only determined by the elastic characteristics of the shell itself, but also ^{is} influenced by the elastic characteristics of the testing machine. This fact is first discussed by the senior author ^{in connection with} ~~in~~ his early paper (Ref. 1).

It is to be noted that the imperfection in the testing machine is then

Concluding Remarks

In the previous paragraphs, the authors have shown that there are equilibrium positions in the buckled shape involving much lower load than the buckling load predicted by classical theory, and thus if the specimen is slightly imperfect, it is reasonable to expect much lower buckle loads

~~order~~ order observed in the laboratory. They have also pointed out that the elastic behavior of the testing machine has a profound influence on the buckling phenomenon and this might be another cause of the large scattering of ~~the~~ ^{the} ~~experimental data~~ ^{data} obtained by different experimenters. However, due to complexity of the problem, the results given in this paper can be only considered as a rough approximation and most of the ~~discussion~~ ^{statement} made ~~is~~ ^{are} qualitative rather than quantitative. To put the new theory on a solid footing, a more accurate solution of the differential equations of equilibrium is necessary. Particular attention must be given to the calculation of the elastic energy stored

of the shell
in a finite
radius

the buckled cylindrical shell, but rather the elastic energy stored.

Further more *and* *will be ref.*
Perhaps, a ~~more~~ ^{more} inquisitive investigator would be pleased by a rigorous proof of the validity of all the large deflection equations. ~~All the~~ ^{the} equations used are ~~intuitive~~ ^{intuitive} arguments rather by systematic ~~reasoning~~. For instance, it is not certain whether the curvature of the shell has to be calculated more accurately by taking into account the second order terms, or the extensions of median surface should be more accurately determined. It is the belief of the ~~present~~ authors that an investigation of these problems

by starting from the general non-linear elasticity theory
 of Cosserat (Ref. 9) and others ~~will be~~^{is} very ~~highly~~ desirable.
 The senior author has already expressed this ~~point~~
 opinion in his 1949 Gibbs Lecture ~~before~~ of the American Mathematical
 Society.

THE BUCKLING OF THIN CYLINDRICAL SHELLS

UNDER AXIAL COMPRESSION

Theodore von Kármán and Hsue-shen Tsien
California Institute of Technology

In two previous papers (Ref. 1 and Ref. 2), the authors have discussed in detail the inadequacy of the classical theory of thin shells in explaining the buckling phenomenon of cylindrical and spherical shells. It was shown that not only the calculated buckling load is 3 to 5 times higher than that found by experiments, but the observed wave pattern of the buckled shell is also different from that predicted. Furthermore, it was pointed out that the different explanations for this discrepancy advanced by L. E. Donnell (Ref. 3) and W. Flügge (Ref. 4) are untenable when certain conclusions drawn from these explanations are compared with the experimental facts. The authors are then led by a theoretical analysis to the conclusion that the buckling of thin cylindrical shells is a nonlinear phenomenon. This conclusion is supported by the fact that the buckling load of a shell decreases very rapidly with increase in wave amplitude once the shell starts to buckle. This characteristic shows, first of all, that there is a release of the elastic energy stored in the shell once the buckling has started, and thus explains the observed rapidity of the buckling process. Furthermore, it also brings in the possibility of a decrease in the buckling load when there are slight imperfections in the test specimen and when there are vibrations during the testing process.

In this paper, the authors will show by means of an approximate

calculation that in case of a thin uniform cylindrical shell under axial compression, the load sustained by the shell drops with increasing deflection. Consequently, they hope that they have thus offered an acceptable explanation of the observed facts.

Stresses in the Median Surface and the
Expression for the Total Energy of the System

Let X and Y be measured in the axial and the circumferential direction in the median surface of the undeformed cylindrical shell and u , v , and w be the components of displacement of a point on the median surface of the shell in the X -direction, the Y -direction, and the radial direction. Then the unit strains in the X and Y -directions, ϵ_x , ϵ_y and the unit shear γ_{xy} at a point in the median surface can be expressed in the following

$$\epsilon_x = \frac{\partial u}{\partial X}, \quad \epsilon_y = \frac{1}{r} \frac{\partial v}{\partial \theta}, \quad \gamma_{xy} = \frac{1}{r} \left(\frac{\partial v}{\partial X} + \frac{\partial u}{\partial \theta} \right)$$

where r is the radius of the shell.

stresses and the strains in the median surface of the shell are, however, related to each other by the following equations:

$$\begin{aligned} \sigma_x &= \frac{E}{1-\nu^2} (\epsilon_x + \nu \epsilon_y) \\ \sigma_y &= \frac{E}{1-\nu^2} (\epsilon_y + \nu \epsilon_x) \\ \tau_{xy} &= \frac{E}{2(1+\nu)} \gamma_{xy} \end{aligned} \quad (2)$$

where E is Young's modulus of elasticity and ν is Poisson's ratio. Therefore by substituting Eq. (1) into Eq. (2), the following connections between the components of stress in the median surface and the components of displacement of the median surface are obtained:

$$\begin{aligned} \sigma_x &= \frac{E}{1+\nu} \left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 v}{\partial x \partial y} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \chi}{\partial x \partial y} + \frac{\partial^2 \eta}{\partial y^2} \right] \\ \sigma_y &= \frac{E}{1+\nu} \left[\frac{\partial^2 u}{\partial x \partial y} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 \psi}{\partial x \partial y} + \frac{\partial^2 \chi}{\partial y^2} + \frac{\partial^2 \eta}{\partial x^2} \right] \end{aligned}$$

$$\tau_{xy} = \frac{E}{2(1+\nu)} \left[\frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 w}{\partial x \partial y} \right]$$

It is generally accepted that the equilibrium conditions of the stresses in the median surface of a thin shell can be approximately expressed by the following equations:

$$\begin{aligned} \frac{\partial \sigma_x}{\partial x} + \frac{\partial \tau_{xy}}{\partial y} &= 0 \\ \frac{\partial \tau_{xy}}{\partial x} + \frac{\partial \sigma_y}{\partial y} &= 0 \end{aligned} \quad (4)$$

These pair of equations can be satisfied by introducing the well-known Airy's stress function, $F(x, y)$ defined by the relations

$$\sigma_x = \frac{\partial^2 F}{\partial y^2}, \quad \tau_{xy} = -\frac{\partial^2 F}{\partial x \partial y}, \quad \sigma_y = \frac{\partial^2 F}{\partial x^2}$$

Eliminating the variables u and v in Eqs. (3) and (6) a relation between Airy's stress function F and the radial component of the displacement, w , is obtained:

$$\frac{\partial^2 F}{\partial x^2} + \frac{\partial^2 F}{\partial y^2} = E \left[\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \chi}{\partial x \partial y} + \frac{\partial^2 \eta}{\partial y^2} \right]$$

This equation expresses the condition of compatibility between stress and strain. When $R \rightarrow \infty$, it reduces to the corresponding equation for a flat plate derived by the senior author (Ref. 5). L. H. Donnell (Ref. 3) first obtained this equation in its present form. With a given form of the radial component of the displacement, w , Eq. (8) gives the induced stresses in the median surface of the shell.

For the corrugate wave panel, the extensural elastic energy, corresponding to these stresses can be written as

$$U = \frac{E}{2(1+\nu)} \int_a^b \int_0^{2\pi} \left[\sigma_x^2 + \sigma_y^2 + 2\tau_{xy}^2 \right] dx dy$$

where a and b are the half wave lengths in the axial and the circumferential directions respectively.

To calculate the bending elastic energy, it is necessary to find the expressions for the change of curvatures and the unit twist of the median surface. In this paper, the following approximate expressions will be used.

$$\chi_x = \frac{\partial^2 w}{\partial x^2}, \quad \chi_{xy} = \frac{\partial^2 w}{\partial x \partial y}, \quad \chi_y = \frac{\partial^2 w}{\partial y^2} \quad (8)$$

In Eq. (8), the neglected terms in χ_x and χ_y are $\frac{\partial^2 w}{\partial x^4}$ and $\frac{\partial^2 w}{\partial y^4}$ respectively. It is assumed in Eq. (8) that those neglected terms differ from the terms retained in Eq. (8) by a factor $\frac{1}{N^2}$, where N is the number of waves in the circumferential direction. For thin cylindrical shells, the value of N is around 10; therefore the neglectation is justified. With these expressions for the change of curvatures and the unit twist of the median surface, the bending energy W_2 for one complete wave panel can be written as

$$W_2 = \frac{t^3 E}{12} \int_0^a \int_0^b \left(\frac{\partial^2 w}{\partial x^2} \right)^2 + \left(\frac{\partial^2 w}{\partial y^2} \right)^2 + 2 \left(\frac{\partial^2 w}{\partial x \partial y} \right)^2 dx dy$$

The work done by the external forces on a complete wave panel of the cylindrical shell can be calculated as the product of the change in length of the shell and the applied force. Therefore the following expression is obtained for one complete wave panel:

$$W_3 = -t \int_0^b (\sigma_x)_{x=a} dy \int_0^a \frac{\partial w}{\partial x} dx \quad (10)$$

The equilibrium condition of the shell can be obtained either by equating the forces and moments on the complete wave panel to zero, or by actually analyzing the moments and the stresses in the median surface of the shell. Using the approximations stated previously, Donnell (Ref. 6) derived the equilibrium equation as

$$E t \nabla^2 W = \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right) + \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right) + \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right)$$

where p is the external radial pressure on the surface of the shell. In the case concerned, $p=0$, then using Eq. (5), the second equation corresponding Airy's stress function ϕ and the radial component of displacement, W is obtained as

$$E t \nabla^2 W = \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right) + \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right) + \frac{1}{2} \left(\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} \right)$$

When $\phi=0$, Eq. (12) reduces to the corresponding equation for a plate.

There are two different ways to solve the problem of the buckling of a thin uniform cylindrical shell under axial compression. The more exact method is to solve Eqs. (6) and (12) simultaneously, using appropriate boundary conditions. The approximate method is to first assume a plausible function for W , with undetermined parameters and then use Eq. (6) to determine the stresses in the median surface of the shell. The energies W_1 , W_2 and W_3 can then be calculated by means of Eqs. (7), (9), and (10). The undetermined parameters can be ascertained by the condition that the sum of energies W_1 , W_2 , and W_3 must be a minimum. This approximate method will be used in the following calculations.

Calculation of the Total Energy

To obtain a plausible form for W , one has to resort to the experimental results. It is observed that, for large values of the wave amplitude, the waves show a so-called diamond shaped pattern. This particular wave shape can be approximately expressed by

$$\frac{W_1}{R} = \cos^2 \frac{(mX+nY)}{2R} \cos^2 \frac{(mX-nY)}{2R}$$

where the squares are introduced to account for the fact that the shell has a definite preference to buckle inward. Eq. (13) can be re-written as

$$\frac{w_1}{R} = \frac{1}{4} + \frac{1}{2} \left[\cos \frac{mX}{R} \cos \frac{nY}{R} + \frac{1}{4} \cos \frac{2mX}{R} + \frac{1}{4} \cos \frac{2nY}{R} \right]$$

On the other hand, the classical theory which is correct for infinitesimal values of the wave amplitude, requires the wave to be of the form

$$\frac{w_2}{R} = \cos \frac{mX}{R} \cos \frac{nY}{R} \quad (15)$$

In order to satisfy this requirement, the wave form assumed in the following calculation is

$$w = f_0 + f_1 \cos \frac{mX}{R} + f_2 \cos \frac{2mX}{R} + f_3 \cos \frac{nY}{R} + f_4 \cos \frac{2nY}{R} + f_5 \cos \frac{mX}{R} \cos \frac{nY}{R} \quad (16)$$

where f_0, f_1, f_2 are unknowns to be determined by conditions of minimum total energy of the system. f_0 is introduced in order to allow the shell to expand radially. The amplitude of the wave pattern defined as the maximum difference in the radial deflection, w is evidently given by f_1 . The wave lengths in the axial and the circumferential direction are $\frac{R}{m}$ and $\frac{R}{n}$ respectively. The circumference of the shell is equal to $2\pi R$. It is evident that no end effect can be accounted for by this form of wave pattern, and therefore the following calculation really corresponds to the case of a very long cylindrical shell. This simplification is justified by the experimental findings of N. Nojima and S. Kanemitsu as reported in a previous paper (Ref. 2). It was found that there is no appreciable length effect when the length of the cylindrical is greater than 1.5 times the radius of the shell. Furthermore, it is seen that by setting $f_0 = f_2 = 0$, Eq. (16) is reduced to Eq. (14); while by setting $\frac{f_1}{4} + \frac{f_2}{2} = 0$ and $f_0 + \frac{f_1}{4} = 0$, Eq.

(16) is reduced to Eq. (15). With other values of these parameters, wave patterns intermediate between these two limits can be obtained.

Substituting Eq. (16) into Eq. (6), the differential equation for Airy's stress function $F(x, y)$ is obtained:

$$\Delta^2 F = \frac{1}{4} f_1^2 n^2 (x^2 - y^2) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 (x^2 + y^2) + \frac{1}{4} f_1^2 n^2 (x^2 - y^2) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 (x^2 + y^2)$$

where $\mu = \frac{m}{n}$, the aspect ratio of the waves. If $\mu > 1$ the waves are longer in the circumferential direction; if $\mu < 1$, the waves are longer in the axial direction. The coefficients in Eq. (17) are given by the following relations:

$$A = \frac{1}{4} f_1^2 n^2 - \left(\frac{1}{2} f_1 + f_2 \right)$$

$$B = \frac{1}{4} f_1^2 n^2$$

$$C = \frac{1}{4} f_1^2 n^2 - \left(\frac{1}{2} f_1 + f_2 \right)$$

$$D = \frac{1}{4} f_1 n^2 \left(\frac{1}{2} f_1 + f_2 \right)$$

$$E = \frac{1}{4} f_1 n^2 \left(\frac{1}{2} f_1 + f_2 \right)$$

and $F = n^2 \left(\frac{1}{2} f_1 + f_2 \right)^2$

The solution of this differential equation can be easily obtained as

$$F = \frac{1}{4} f_1^2 n^2 \left(\frac{x^2}{2} - \frac{y^2}{2} \right) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 \left(\frac{x^2}{2} + \frac{y^2}{2} \right) + \frac{1}{4} f_1^2 n^2 \left(\frac{x^2}{2} - \frac{y^2}{2} \right) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 \left(\frac{x^2}{2} + \frac{y^2}{2} \right) + \frac{a}{2} x^2 + \frac{\beta}{2} y^2$$

Using Eq. (5), the stress components in the median surface can be written

$$\sigma_x = \frac{1}{4} f_1^2 n^2 (x^2 - y^2) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 (x^2 + y^2) + \frac{1}{4} f_1^2 n^2 (x^2 - y^2) + \frac{1}{2} f_1 f_2 n^2 xy + \frac{1}{4} f_2^2 n^2 (x^2 + y^2) + \frac{a}{2} x^2 + \frac{\beta}{2} y^2$$

(20)

$$\begin{aligned}
 & \frac{1}{2} \left(\sigma_x^2 + \sigma_y^2 + \sigma_z^2 + \tau_{xy}^2 + \tau_{yz}^2 + \tau_{zx}^2 \right) \\
 & + \frac{\mu}{1+\mu} \left(\sigma_x + \sigma_y + \sigma_z \right)^2 \\
 & \tau_{xy} = \frac{1}{2} \left(\sigma_x - \sigma_y \right) \sin 2\theta \\
 & \tau_{yz} = \frac{1}{2} \left(\sigma_y - \sigma_z \right) \sin 2\theta \\
 & \tau_{zx} = \frac{1}{2} \left(\sigma_z - \sigma_x \right) \sin 2\theta
 \end{aligned}$$

If σ is the average stress, then $\sigma = \frac{1}{3}(\sigma_x + \sigma_y + \sigma_z)$ is the average compression stress σ in the axial direction. It can be easily seen from Eq. (20) that

$$\beta = -\sigma \tag{21}$$

Using Eq. (3), the following expressions for $\frac{\partial U}{\partial x}$ and $\frac{\partial V}{\partial y}$ can be obtained:

$$\begin{aligned}
 \frac{\partial U}{\partial x} &= \frac{1}{E} (\sigma_x - \nu \sigma_y) - \frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2 \\
 \frac{\partial V}{\partial y} &= \frac{1}{E} (\sigma_y - \nu \sigma_x) - \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{w}{R}
 \end{aligned} \tag{22}$$

By substituting Eqs. (16) and (20) into Eq. (22), it is found that

$$\begin{aligned}
 \frac{\partial U}{\partial x} &= \frac{1}{E} \left(\sigma_x - \nu \sigma_y \right) - \frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2 \\
 \frac{\partial V}{\partial y} &= \frac{1}{E} \left(\sigma_y - \nu \sigma_x \right) - \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2 + \frac{w}{R}
 \end{aligned} \tag{23}$$

Since y is measured along the circumference of the shell, V must be a periodic function of y ; therefore, the constant term in $\frac{\partial V}{\partial y}$ must be equal to zero. Or

$$\int_0^{2\pi} \left(\frac{\partial V}{\partial y} \right) dy = 0$$

This is the condition for the determination of α .

Using Eqs. (7), (20) and (24), the extensional energy W_1 of the shell is obtained as

$$\begin{aligned}
 \frac{1}{2} \int_{-a/2}^{a/2} \left[\frac{1}{2} \left(\frac{d^2 w}{dx^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dz^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dy} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dz} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy dz} \right)^2 \right] dx dy dz \\
 + \frac{\mu^4}{(1+\mu^2)^2} D^2 + \frac{\mu^4}{(1+\mu^2)^2} G^2 + \frac{\mu^4}{16(1+\mu^2)^2} H^2 \Big]
 \end{aligned}$$

Using Eqs. (9) and (16), the bending energy W_2 of the shell can be calculated as

$$\frac{1}{2} \int_{-a/2}^{a/2} \int_{-a/2}^{a/2} \int_{-a/2}^{a/2} \left[\frac{1}{2} \left(\frac{d^2 w}{dx^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dz^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dy} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dz} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy dz} \right)^2 \right] dx dy dz$$

The lowering of the potential of the applied forces can be obtained by means of Eqs. (10), (20), (23) and (24). The result is

$$\begin{aligned}
 \frac{1}{2} \int_{-a/2}^{a/2} \int_{-a/2}^{a/2} \int_{-a/2}^{a/2} \left[\frac{1}{2} \left(\frac{d^2 w}{dx^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dz^2} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dy} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dx dz} \right)^2 + \frac{1}{2} \left(\frac{d^2 w}{dy dz} \right)^2 \right] dx dy dz \\
 - 2V \frac{\sigma}{E} \left(f_0 + \frac{1}{4} f_1 \right) \Big]
 \end{aligned}$$

Relation between the Compression Stress and the Amplitude of Waves

To find the relation between the compression stress and the amplitude of the waves, the conditions which will make the sum of the energies W_1 , W_2 , and W_3 a minimum have to be obtained. It was found that the calculations can be simplified to a certain extent by first using the condition that the sum of energies must be a minimum with respect to

Or

$$\frac{\partial}{\partial f_0} (W_1 + W_2 + W_3) = 0 \quad (28)$$

This condition determines a relation between f_0 and f_1 and f_2 , which can be written as:

$$f_0 + \frac{1}{4} f_1 = \pi^2 \left(\frac{3}{64} f_1^2 + \frac{1}{16} f_1 f_2 + \frac{1}{16} f_2^2 \right) - \nu \frac{\sigma}{E} \quad (29)$$

Using this relation and Eq. (24), it is easily seen that $d=0$. In other words, the shell will expand radially to such an extent that the average of the circumferential stress $\bar{\sigma}_\theta$ is equal to zero. Substituting Eq. (29) into the expressions for W_1 , W_2 and W_3 as given by Eqs. (25), (26) and (27) and using Eq. (18), the total energy of the system is expressed finally in the following form:

$$\begin{aligned}
 W = & \frac{1}{2} \int_0^{2\pi} \int_0^L \left[\frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 \right. \\
 & + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 \\
 & + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 \\
 & + \left. \left[\left(\frac{1}{32} + \frac{1}{4} \frac{\mu^6}{(1+\mu^2)^2} \right) f_1^2 + \frac{1}{8} f_1 f_2 + \frac{1}{8} f_2^2 \right] + \right. \\
 & \left. + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 + \frac{1}{2} \left(\frac{1}{R} \frac{\partial w}{\partial \theta} \right)^2 \right] d\theta dz
 \end{aligned} \quad (30)$$

The equilibrium conditions are then obtained by differentiating the expression for total energy, Eq. (30), with respect to f_1 and f_2 , and then set these expressions equal to zero. The results can be written in a simpler form by introducing the following parameters:

$$\zeta = \frac{f_2}{f_1}, \quad \eta = \pi^2 \frac{1}{R}, \quad \xi = f_1 \frac{R}{t} = \frac{\delta}{t} \quad (31)$$

where δ is the wave amplitude of the buckled shape of the cylindrical shell. Then the equilibrium conditions are

$$A_1 = -\frac{\xi}{3(1-\nu^2)} \eta^2 \left\{ 2(1+\mu^4) - \frac{1}{2}(1+\mu^2)^2 \right\}$$

$$A_0 = -\frac{2}{3(1-\nu^2)} \eta^2 \left\{ (1+\mu^4) - \frac{1}{4}(1+\mu^2)^2 \right\} = -\frac{A_1}{2}$$

Substituting into Eq. (31) it is seen that $f_2 = -\frac{1}{2} f_1$, or $f_2 = -\frac{1}{2} f_1$.

Putting this relation between f_1 and f_2 into Eq. (14), the wave pattern is reduced to that represented by Eq. (13), i.e., the classical wave pattern for infinitesimal wave amplitude.

With a given value of μ and η , the coefficients for various values of the wave amplitude ξ can be first calculated by using the Eq. (34). Then Eq. (33) can be solved for ρ corresponding to this particular set of values of μ and η at various wave amplitude ξ . When the value of ρ is known, Eq. (32) can be used to calculate the corresponding value of the compression stress $\frac{\sigma R}{Et}$. It is found, however, that the following expression for the compression stress $\frac{\sigma R}{Et}$ which is taken from Eq. (3) by eliminating the third powers of ρ is more suitable for numerical computations:

$$\frac{\sigma R}{Et} = \left\{ \frac{1}{\eta} \frac{\mu^2}{(1+\mu^2)^2} + \frac{1}{12(1-\nu^2)} \frac{\eta(1+\mu^2)^2}{\mu^2} \right\}$$

$$+ \frac{1}{12(1-\nu^2)} \frac{\eta^3}{\mu^2} + \frac{1}{12(1-\nu^2)} \frac{\eta^5}{\mu^2} + \frac{1}{12(1-\nu^2)} \frac{\eta^7}{\mu^2} + \dots$$

$$+ \frac{1}{12(1-\nu^2)} \frac{\eta^9}{\mu^2} + \frac{1}{12(1-\nu^2)} \frac{\eta^{11}}{\mu^2} + \frac{1}{12(1-\nu^2)} \frac{\eta^{13}}{\mu^2} + \dots$$

$$+ \frac{1}{12(1-\nu^2)} \frac{\eta^{15}}{\mu^2} + \frac{1}{12(1-\nu^2)} \frac{\eta^{17}}{\mu^2} + \dots$$

Therefore, when $\xi \rightarrow 0$, i.e., when the wave amplitude becomes very small, Eq. (35) reduces to

$$\left(\frac{SR}{Et}\right)_{\xi \rightarrow 0} = \frac{1}{\eta} \frac{\mu^2}{(1+\mu^2)^2} + \frac{1}{12(1-\nu^2)} \frac{1}{\eta} \frac{\mu^2}{(1+\mu^2)^2} \quad (36)$$

$$M_{\min} \left(\frac{SR}{Et}\right)_{\xi \rightarrow 0} = \frac{1}{\sqrt{3(1-\nu^2)}} \quad (37)$$

deflections. This minimum value is obtained when

$$\eta \frac{1 + \mu^2}{\mu^2} = 2\sqrt{3(1-\nu^2)} \quad (38)$$

It is interesting to notice that for infinitesimal wave amplitude, the minimum value of average compression stress is not determined by separate parameters η and μ , but by a combined parameter shown in Eq. (38).

These calculations were carried out for two values of the parameter μ , the ratio of the wave lengths in circumferential direction and in axial direction. These values of μ are 1 and 0.5. The value 1 was chosen because the experiments indicate that at large values of wave amplitude, the diamond waves have almost equal sides. The value 0.5 was chosen to investigate the possibility of occurrence of narrow waves. The results of these computations are shown in Fig. 2 and Fig. 3, where the compression stress $\frac{SR}{Et}$ is plotted against the wave amplitudes ξ . The parameter in the figures is η . The values written in the parenthesis after η is the actual number of waves N in circumferential direction for $R/t = 1000$. For a given value of η and μ , i.e., a fixed size of the wave, the load sustained by the shell, $\frac{SR}{Et}$ first decreases as the wave amplitude, ξ , is increased. After a minimum is reached, the load will rise with increase in wave amplitude. When the waves are larger, the initial buckling

load, i.e., the value of $\frac{\sigma R}{E t}$ at $\xi=0$, is higher. However, the minimum load reached tends to a lower value, except for $\eta < 0.169$ and $\mu=1.0$. For $\mu=0.5$, the lowest value of the minimum load is not yet reached at $\eta=0.081$.

The Relation between the Compression Stress
and the Shortening in the Axial Direction

Although the load characteristic of the cylindrical shell shown in the Figs. 2 and 3 give the possible equilibrium relations between load and amplitude of the deflection wave, the actual behaviour of a specimen in a testing machine cannot be directly seen from these figures. In a testing machine, the only factor under the control of the operator is the distance between the end plates; this is the geometrical restraint the specimen must conform. Therefore, in order to determine the behaviour of the specimen the compression stress will have to be plotted as function of the end shortening. The unit end shortening, ξ , i.e., the total shortening in one wave length of the shell in axial direction divided by the wave length, can be easily calculated from Eq. (23). It is found that

$$\frac{\xi R}{t} = \frac{\sigma R}{E t} + \frac{\mu^2}{16} \xi (\eta^2) \left(\rho^2 + \rho + \frac{3}{4} \right) \quad (39)$$

This equation for the unit end shortening contains only quantities already known. As the values of ξ and $\frac{\sigma R}{E t}$ in Figs. 4 and 5, the compression stress $\frac{\sigma R}{E t}$ plotted against the unit end shortening ξ for $\mu=0.5$ and $\mu=1.0$, respectively. It is immediately clear from these two figures that if the buckling process follows the curves drawn, after the shell starts to buckle the end shortening has to decrease. In other words, the end plates of the testing machine have to move apart. Therefore, the process of buckling in this region is highly unstable, since before the operator has

times to separate the end plates, the shell will jump to the point P (Figs. 4 or 5) which has the same end shortening as the starting point of the buckling process, but has a much lower compression stress. This jump in equilibrium positions involves a release of elastic energy and thus explains the rapidity of the buckling process observed and the accompanied vibration.

However, it is still difficult to say whether the shell will jump to a state with almost square waves, as shown in Fig. 4, or to a state with narrow waves, as shown in Fig. 6. Superficially, one might conclude that the narrow waves are the more probable shape because it gives a much lower compression stress, as can be seen by comparing Figs. 4 and 5. But, according to the fundamental concept of mechanics, the true criterion for the most probable equilibrium position compatible with a given value of the end shortening is that the elastic energy stored in the shell should be the lowest. An approximate calculation of the elastic energy of the shells shows that for values of $\eta < 0.12$, the occurrence of the narrow waves is improbable, because the elastic energy stored is higher than that for the square waves at same value of the end shortening. However, for $\frac{ER}{t}$ near 0.6, and $\eta \geq 0.12$ the elastic energy stored in the shell for the narrow waves is comparable to that for the square waves at the same value of the end shortening. This indicates the possibility of the appearance of narrow waves during the very initial stages of the buckling process.

In any case, it is certain that there are equilibrium positions of a buckled cylindrical shell which involve much lower average compression stress $\frac{\sigma R}{Et}$ than that at the beginning of buckling. For instance, in the case of square wave pattern, the lowest compression stress is given by

$$\frac{\sigma}{E} = 0.194 \frac{t}{R} \quad (40)$$

Incidentally, this value corresponds closely to most of the experimental results obtained by L. H. Donnell (Ref. 3) and E. E. Lundquist (Ref. 7).

The corresponding value of the parameter η which determines the number of waves is equal to 0.225. In case of $R/t = 1000$, the number of waves, N , will be 15 which also agrees well with the experimental evidence. For this particular value of the radius to thickness ratio, the number of waves along the circumference decreases from the $N = 26$ at the beginning of the buckling to $N = 15$ at the calculated minimum buckling stress. This gradual increase in the size of waves with the unit shortening is also observed by the experiments reported in an earlier paper (Ref. 2).

It is particularly interesting, however, to trace the gradual change in the wave pattern during the buckling process. Figs. 6 and 7 show the lines of equal deflection of the wave surfaces corresponding to different equilibrium states for two values of the aspect ratio of the wave pattern, $\mu = 1.0$ and $\mu = 0.5$. These particular equilibrium states are denoted in Figs. 2, 3, 4 and 5 by a small circle in order to indicate their relative position during the buckling process. It is seen that there is a rapid shift from the rectangular waves bounded by lines, $x = \text{const.}$, and $y = \text{const.}$, as predicted by the classical theory for infinitesimal wave amplitudes, to staggered rows of circular or elliptical waves. Whereas, the rectangular waves are directed alternatively inward and outward, the circular or elliptical waves are all directed inwards. The transition is practically completed for $\xi = 4$ or 6 , i.e., when the wave amplitude is only 4 or 6 times the thickness of the shell. The occurrence of such inwardly directed circular and elliptical waves at this stage of the buckling process is in good agreement with the experimental observations (Ref. 2). If the experiment $(\xi \sim 30)$ is continued to larger deflections, these staggered waves

obtain characteristic diamond shapes. The present approximate theory fails to give these sharp diamond shaped waves. It is obviously not sufficiently exact for such large deflections. Furthermore, when these diamond shaped waves occur, the load on the specimen actually falls to a very low value such as $\frac{QR}{Et} \approx 0.06$, whereas the theory shows a slight increase of the stress at least for the case $\mu = 1.0$. Therefore, the present calculation can be only considered as a good approximation to the earlier stages of buckling when the wave amplitude is only a few times the thickness of the shell. Nevertheless, it reproduces the characteristic features of the buckling process observed in the laboratory.

The Effect of the Elastic Characteristic of
the Testing Machine on the Buckling Phenomenon

It was stated in the previous paragraph that the state of the specimen is determined by the distance between the end plate and that this distance is the independent parameter controlled by the experimenter. This statement is correct only insofar the elasticity in the mechanism of the testing machine is neglected. Since there is always a certain amount of elastic deflection in the loading mechanism and this deflection is a function of the load. Hence, if, for example, the loading crank is held at a certain position, the compression force acting on the specimen will force the end plates apart and thus reduce the amount of end shortening of the specimen. The actual shortening is determined by the load-deflection characteristics of the specimen and the testing machine. Assuming that the testing machine has a linear elastic characteristic, the compression load is related to the end shortening by parallel straight lines, each line corresponding to, say, a constant number of turns of the loading crank. If the loading crank of

the machine is held at a fixed position, corresponding values of the compression load and end shortening of the specimen must lie on the straight line for this crank position. If the load-end shortening characteristics of the specimen itself are given, it is evident that the equilibrium positions of the entire system are determined by intersections of the curves representing the characteristics of the specimen with the straight lines representing the characteristics of the machine.

Fig. 8 shows representative curves for the characteristics of the specimen and two families of straight lines representing the characteristics of two different testing machines. It is evident that after the maximum or initial buckling load is reached, the shell will jump to a new equilibrium position involving much lower compression load. But this new equilibrium position is determined not only by the load-end shortening relationship and also by the elastic characteristic of the testing machine. A more elastic machine will give a set of characteristic straight lines with smaller slopes. Therefore, in case of curve A (Fig. 8), a more elastic machine will make the shell to jump to a higher load, while in case of curve B, a more elastic machine will make the shell to jump to a lower load. This influence of the elasticity of the testing machine has been discussed by the senior author in connection with the plastic buckling of columns (Ref. 8).

Concluding Remarks

In the previous paragraphs, the authors have shown that there are equilibrium positions in the buckled shape involving much lower load than the buckling load predicted by the classical theory, and thus if the specimen is slightly imperfect, it is reasonable to expect much lower buckling loads. They have also pointed out that the elastic characteristic

of the testing machine might have quite a large influence on the buckling process and this might be another cause of the large scattering of the data obtained by different experimenters. However, due to the complexity of the problem, the results given in this paper can be only considered as a rough approximation and most of the statements made are qualitative rather than quantitative. To put the new theory on a solid footing, a more accurate solution of the differential equations of equilibrium is necessary. Particular attention must be given to the calculation of the elastic energy stored in the shell, because it is found that the most probable equilibrium depends on the magnitude of the elastic energy stored in the various equilibrium positions compatible with the constraint exerted by the loading process.

Furthermore, an inquisitive mind will, perhaps, be pleased by a rigorous proof of the validity of all the large deflection equations. These equations are established by intuitive arguments, not by systematic reasoning. For instance, due to the appearance of sharp curvatures in the diamond shaped wave surfaces at large deflections, it is not certain whether the curvature of the shell has to be calculated more accurately by taking into account the second order terms, or the extensions of the median surface should be more accurately determined. It is the belief of the authors that an investigation of these problems by starting from the general non-linear theory of elasticity developed by G. Kirchhoff, J. Boussinesq and others is very desirable. The recent work by R. Kappus (Ref. 9) is a noteworthy contribution in this field of investigation. The senior author has already expressed this opinion in his 1939 Gibbs Lecture (Ref. 10) given before the American Mathematical Society.

Take-off from Satellite Orbit

Rough draft 2

Take-off from Satellite Orbit

H. C. Tsiou

Summary

The mass ratio or the characteristic velocity for a take-off at a space ship from the satellite orbit is computed for two cases: the radial thrust and the circumferential thrust. The circumferential thrust is much more efficient in that the required mass ratio is much less than for the radial thrust. Both cases show, however, an increase of the required ^{mass ratio and the} characteristic velocity with a reduction in acceleration. With circumferential thrust, the characteristic velocity increases by a factor of two when the acceleration is reduced from $\frac{1}{2}g$ to $\frac{1}{3000}g$.

it is convenient to have

[illegible]

Basic Equations

The problem considered is the motion of a space ship under the action of its rocket thrust and the gravitational attraction of the earth. The rocket thrust is assumed to be directed along the line of sight of the earth. The magnitude of gravitational attraction at the starting satellite orbit r_0 (Eq 1), then the equations of motion of the space ship are

$$\frac{d^2 r}{dt^2} = R + r \left(\frac{d\theta}{dt} \right)^2 - g \left(\frac{r_0}{r} \right)^2$$

and

$$\frac{d}{dt} \left(r^2 \frac{d\theta}{dt} \right) = r \Omega$$

given by

$$r_0 \left(\frac{d\theta}{dt} \right)_0^2 = g \quad (3)$$

Initially, the radial velocity is zero, i.e.,

$$\left(\frac{dr}{dt} \right)_0 = 0 \quad (4)$$

These are the initial conditions for the space ship to have sufficient

power to flight, the sum of the kinetic energy and the potential energy of the space ship must be constant. Thus at $t = t_1$

$$\frac{1}{2} \left[\left(\frac{dr}{dt} \right)^2 + \left(r \frac{d\theta}{dt} \right)^2 \right] - \frac{1}{2} \frac{v_0^2}{r} = 0 \quad (5)$$

With any specified variation of the thrust forces R and C as functions of time, the above system of equations determine completely the take-off trajectory of the space ship. In the following sections, two special cases of practical significance will be discussed in detail: the case $C = 0$ i.e. out, $\hat{C} = 0$, purely radial thrust and $C = R$ i.e. $\hat{C} = \hat{R}$ a constant, purely circumferential thrust.

Radial Thrust

If the thrust is always radial and is proportional to the instantaneous mass of the vehicle, a non-dimensional thrust factor μ can be introduced as

$$R = \mu g \quad (6)$$

Furthermore, let

$$\xi = r/r_0, \quad \tau = \sqrt{\frac{g}{r_0}} t \quad (7)$$

Then Eqs (1) and (2) can be written in the non-dimensional form as

$$\frac{d^2 \xi}{d\tau^2} = \mu + \xi \left(\frac{d\theta}{d\tau} \right)^2 - \frac{1}{\xi^2} \quad (8)$$

and

$$\frac{d}{d\tau} \left(\xi^2 \frac{d\theta}{d\tau} \right) = 0 \quad (9)$$

Eq (9) can be immediately integrated and by using the initial condition $\dot{\theta} = \dot{\theta}_0$ at $\tau = 0$ we get

$$\frac{d\theta}{d\tau} = \frac{\dot{\theta}_0}{\xi^2} \quad (10)$$

By substituting the equation into Eq (8), the final equation for ξ is

$$\frac{d^2 \xi}{d\tau^2} = \mu + \frac{1}{\xi^3} - \frac{1}{\xi^2} \quad (11)$$

The non-dimensional radial velocity is $d\rho/d\tau$. This is related to the physical radial velocity dr/dt as follows

$$\frac{dr}{dt} = \sqrt{g r_0} \frac{d\rho}{d\tau} \quad (11)$$

Eq (10) can be rewritten as

$$\frac{d}{d\tau} \left(\frac{d\rho}{d\tau} \right)^2 = u + \frac{1}{\tau} - \frac{1}{\tau^2}$$

Since $d\rho/d\tau = 0$ when $\tau = 0$ and $\rho = 1$ according to Eq. (6), the result of integrating the above equation is

$$\left(\frac{d\rho}{d\tau} \right)^2 = 2\mu(\rho - 1) + \left(1 - \frac{1}{\rho^2} \right) - 2 \left(1 - \frac{1}{\rho} \right) \quad (12)$$

Hence the non-dimensional time τ can be calculated as a function of the radius ρ as follows

$$\tau = \int_1^\rho \frac{\rho d\rho}{\sqrt{(\rho - 1)(2\mu\rho^2 - \rho + 1)}} \quad (13)$$

With Eqs. (9) and (12), the end condition of Eq. (5) can be written as

$$\frac{1}{2} \left[\left(2\mu(\rho_1 - 1) + \left(1 - \frac{1}{\rho_1^2} \right) - 2 \left(1 - \frac{1}{\rho_1} \right) \right) + \frac{1}{\rho_1^2} \right] - \frac{1}{\rho_1} = 0$$

Or simply

$$\rho_1 = 1 + \frac{1}{2\mu}$$

Then the velocities at the end of acceleration period are

$$\left(\frac{dr}{dt} \right)_1 = \sqrt{g r_0} \frac{1}{1 + \frac{1}{2\mu}}$$

$$\left(r \frac{dr}{dt} \right)_1 = \sqrt{g r_0} \frac{1}{1 + \frac{1}{2\mu}}$$

the T_1 for a forced flight can be obtained from Eq. (13) by setting the upper limit of integration to S_1 . Thus

$$T_1 = \frac{2}{\mu} \left[\frac{\sqrt{2\mu+1}}{2\mu+1} + F\left(\frac{1}{\sqrt{2\mu}}, \cos^{-1} \frac{1}{2\mu+1}\right) + E\left(\frac{1}{\sqrt{2\mu}}, \sin^{-1} \frac{1}{2\mu+1}\right) \right] \quad (14)$$

where F and E are the elliptical integrals of first kind and second kind respectively.*

If $M(t)$ is the instantaneous mass of the space ship, and c the effective exhaust velocity of the rocket, then

$$RM = \mu g M = -c \frac{dM}{dt} = -c \sqrt{\frac{g}{r_0}} \frac{dM}{dZ}$$

Therefore the mass ratio M_0/M_1 can be calculated as follows:

$$\log(M_0/M_1) = \frac{\sqrt{g r_0}}{c} \mu T_1$$

By using the result of Eq. (14),

$$\log(M_0/M_1) = \frac{2\sqrt{2\mu+1}}{2\mu+1} + \sqrt{\frac{2}{\mu}} \left[F\left(\frac{1}{\sqrt{2\mu}}, \cos^{-1} \frac{1}{2\mu+1}\right) + E\left(\frac{1}{\sqrt{2\mu}}, \sin^{-1} \frac{1}{2\mu+1}\right) \right] \quad (15)$$

When the acceleration is very large, $\mu \gg 1$, the integrand in Eq. (13) can be expressed in terms of the parameter $\alpha = \frac{1}{2\mu+1}$ as

$$\frac{c}{\sqrt{g r_0}} \log(M_0/M_1) = 1 + \frac{1}{2\alpha^2} - \frac{1}{4\alpha^4} + \dots \quad (16)$$

The relation of Eqs. (17) and (16) is plotted in Fig. 2. For $\mu = \frac{1}{2}$, the mass ratio becomes infinite. The reason is that at this value

The author is indebted to Dr. Y. T. Wu who kindly supplied the solution of Eq. (14).

of acceleration, there is a radial fraction where the thrust force is equal to the gravitational attraction and one further increase in the energy of the vehicle can occur. Therefore the radial thrust per unit mass, if maintained constant throughout the powered flight, should be larger than $1/2 g$. With increasing thrust, the required mass ratio for a given mission decreases. This is in contrast to the opinion that for take-off from orbit only very small thrust is required. The strong dependence of mass ratio when the acceleration factor is contrary to opinion that for take-off from orbit only very small thrust is required.

Circumferential Thrust

If the thrust is always circumferential and proportional to the mass of the vehicle, then

$$\Theta = v g \quad (19)$$

By using the same non-dimensional variables as defined in Eq (6), the equations of motion are

$$\frac{d^2 \rho}{d\tau^2} = \rho \left(\frac{d\theta}{d\tau} \right)^2 - \frac{1}{\rho^2} \quad (20)$$

$$\frac{d}{d\tau} \left(\rho^2 \frac{d\theta}{d\tau} \right) = 4 \rho \quad (21)$$

The initial conditions of Eqs (3) and (4) are

$$\left(\frac{d\theta}{d\tau} \right)_0 = 1, \quad \left(\frac{d\rho}{d\tau} \right)_0 = 0, \quad \text{at } \rho=1, \tau=0 \quad (22)$$

Therefore Eq (20) gives another initial condition that

$$\left(\frac{d^2 \rho}{d\tau^2} \right)_0 = 0 \quad (23)$$

By eliminating θ from Eqs (20) and (21)

$$\frac{d^2 \rho}{dt^2} + \frac{d\rho}{dt} = \dots$$

This is a third order differential equation with three initial conditions. The general solution can be obtained by the method of variation of parameters. The solution is thus centered around approximations that are valid for very large values of v .

For very large values of v , the acceleration period is expected to be very short. The value of ρ must be very close to the initial value of unity. By taking ρ to be unity, Eq. (24) becomes

$$\frac{d}{dt} \left(\frac{d^2 \rho}{dt^2} + 1 \right)^{\frac{1}{2}} = v$$

Then

$$\frac{d^2 \rho}{dt^2} + 1 = C^2 + 2CvE + v^2 E^2$$

where C is the integration constant. C , however, must be 1 because of the initial condition of Eq. (23). The appropriate approximate solution for ρ for very large v is thus

$$\rho \approx 1 + \frac{1}{3} v E^3 + \frac{1}{12} v^2 E^4 \quad (25)$$

To obtain higher terms in this power series, the method of successive approximations may be used. The calculation is somewhat lengthy and therefore will not be reproduced here. The result is

$$\rho = 1 + \frac{1}{3} v E^3 + \frac{1}{12} v^2 E^4 - \frac{\pi}{16} E^5 - \frac{23\pi^2}{360} E^6 + \dots \quad (26)$$

By using the result of Eq. (26), the radial velocity is obtained by differentiation. Then Eq. (20) gives the circumferential velocity. The end condition of Eq. (5) can be modified into the following more convenient form by multiplying it by r^2 .

$$0 = \left[\left(\rho \frac{d\rho}{d\tau} \right)^2 + \left(\rho^2 \frac{d\theta}{d\tau} \right)^2 - 2\rho \right],$$

substituting τ_1 is obtained:

$$0 = -1 + 24\tau_1 + 4\tau_1^2 - \frac{2}{3}4\tau_1^3 + 4\tau_1^4 + \frac{4}{30}(1+24\tau_1^2)\tau_1^5 - \frac{4}{90}(4-13\tau_1^2)\tau_1^6 + \dots \quad (27)$$

is a new system and can be determined using the new parameter x (defined as follows).

$$\frac{c}{4g_0} \log(M_0/M_1) = 4\tau_1 = x \quad (28)$$

Since the calculation is designed for large values of τ , expansion of x should be a series in even powers of τ .
 τ_1 (29)

$$x = x^{(0)} + x^{(2)} + x^{(4)} + \dots \quad (30)$$

where $x^{(0)}$, $x^{(2)}$ and $x^{(4)}$ are constants independent of τ by

the following set of equations results:

$$x^{(0)2} + 2x^{(0)} - 1 = 0$$

$$x^{(2)} = \frac{1}{2(1+x^{(0)})} \left[\frac{2}{3} x^{(0)3} - x^{(0)4} - \dots \right]$$

(The acceleration will be very small and)

$$x^{(0)} = \sqrt{2} - 1 = 0.41421$$

$$x^{(1)} = 0.002349$$

$$x^{(2)} = -0.00004791$$

this completes the calculation of mass ratio for large values of the acceleration factor γ .

For the other extreme case of very small values of γ , it is to be expected that in Eq. (134) the term $\rho^3 \frac{d\rho}{dt^2}$ will be very much smaller than ρ . Therefore a good approximation of Eq. (134) at small γ is

$$\frac{d}{dt}(\rho)^{\frac{1}{2}} = \gamma \rho \quad \text{or} \quad \frac{1}{2} \frac{d\rho}{\rho^{3/2}} = \gamma dt$$

The solution of this equation with the initial condition $\rho=1$ at $t=0$ is

$$\rho = \frac{1}{(1-\gamma t)^2} \quad (35)$$

$$\frac{d\rho}{dt} = \frac{2\gamma}{(1-\gamma t)^3}, \quad \frac{d^2\rho}{dt^2} = \frac{6\gamma^2}{(1-\gamma t)^4} \quad (36)$$

At $t=0$, the radial velocity and the radial acceleration are thus not zero as required by the initial conditions of Eqs. (22) and (23). These are however very small, because γ is very small. Therefore the solution of Eq. (35) is a good approximation to the exact solution.

To the same approximation, Eq. (134) becomes

$$\rho \frac{d\rho}{dt} = \frac{1}{\rho^{1/2}} = (1-\gamma t) \quad (37)$$

... force per unit mass $\gamma(\frac{d\rho}{dt})^2$ practically balances the gravitational attraction at every instant. The end condition of Eq. (35) can then

be written as

$$\frac{6x^2}{(1-x)^6} - (1-x)^2 = 0 \quad (2)$$

where x is γv . The appropriate solution for x is then

$$x = 1 - (2v)^{1/4} \quad (3)$$

Since the mass ratio M_0/M_1 is related to x by Eq. (28), Eq. (39) actually gives the mass ratio for escaping the gravitational field with any small acceleration.

The parameter x is plotted against v in Fig. 3, using both Eq. (39) and Eq. (28) and Eq. (39). When v approaches 0, x approaches 1. When v is very large, x approaches $\sqrt{2}-1$. As v increases, x and hence the mass ratio M_0/M_1 decrease monotonically. Therefore, as in the result for purely radial thrust, there is a strong influence of the magnitude of acceleration on the required mass ratio. However as far as decreasing the mass ratio is concerned, there is no appreciable advantage in using v greater than $1/2$.

Discussion

By comparing the results for radial and circumferential thrust, it is seen that the required mass ratio for radial thrust is more than twice that for circumferential thrust. Furthermore, in case of radial thrust, the ratio of thrust to the instantaneous mass, if maintained constant, must be larger than $1/8$. In case of circumferential thrust, no such limit exists. Therefore circumferential thrust is definitely preferred.

The quantity $c \log(M_0/M_1)$ is a measure of ^{the} performance or the

capability of the vehicle. It has the dimension of a velocity and is actually the increase of velocity which the vehicle is capable of in a given thrust gradient. The quantity λ is called the thrust-to-weight ratio of the vehicle. Let this be denoted by V_0 . Then for the case of circumferential thrust, Eq (28) gives

$$V = c \log(M_0/M_1) = \sqrt{g r_0} \lambda = \frac{S}{\sqrt{2} \lambda} \lambda \quad (40)$$

where S is the escape velocity of the vehicle. λ is the ratio of the radius of the satellite orbit and the earth. S is equal to 11.2 km/sec. Fig. 3 then shows that by decreasing the radius of the orbit λ the required velocity V , will increase by a factor of two. This is a very important point for the designers of space ships.

Take-Off From Satellite Orbit

H. S. Tsien^{*}

Summary

The mass ratio or the characteristic velocity for the take-off of a space ship from the satellite orbit is computed for two cases: the radial thrust and the circumferential thrust. The circumferential thrust is much more efficient in that the required mass ratio is much less than for the radial thrust. Both cases show, however, an increase of the required mass ratio and the characteristic velocity with a reduction in acceleration. With circumferential thrust, the characteristic velocity increases by a factor of two when the acceleration is reduced from $1/2$ g to $1/3000$ g.

^{*}Robert H. Goddard Professor of Jet Propulsion

For take-off of a rocket from the earth surface, it is convenient to have the initial trajectory in the vertical direction and then the thrust should be ^{to give an appropriate acceleration} considerably larger than the initial weight of the rocket. ~~depending on~~ the relative magnitudes of the aerodynamic drag and the weight, the initial ratio of the thrust and the weight should be between 2 and 3 for minimum expenditure of the propellant. The situation is quite different for a space ship taking off from the satellite orbit: In a satellite orbit, the gravitational attraction is completely balanced by the centrifugal force, and the vehicle is effectively in a weightless state. This fact has led many fanciers of interplanetary travel to conclude that take-off from satellite orbit requires only a very minute thrust. For instance, L. Spitzer (Ref. 1) proposed a nuclear power plant for ^a his space ship to be accelerated at only $1/3000$ g. Another example is the extensive discussion of interorbital transport techniques by H. Preston - Thomas (Ref. 2) based upon the assumption of equally small acceleration. On the other hand, W. von Braun (Ref. 3) seems to prefer a very much larger acceleration of approximately $1/2$ g for take-off from the satellite orbit.

The magnitude of the acceleration has a strong bearing on the optimum type of power plant to be used: The ion-beam rocket is only possible for very small acceleration, while for moderate acceleration, chemical rocket is required. Therefore the question of the magnitude of acceleration is an important one for interplanetary flight. The purpose of this note is to ~~demonstrate clearly~~ the relation between the acceleration and the thrust required for escape from the earth's gravitational field, starting from the satellite orbit. It is hoped that the present investigation will give the future generation of astronautical engineers a ~~more~~ rational basis for designing space ships.

Basic Equations

The problem considered is the motion of a space ship under the influence of the rocket thrust and the gravitational attraction of a single massive body, say the earth. Then if the rocket thrust is in the plane of trajectory, the trajectory of the space ship will remain in a plane. Let the position of the ship at any time instant t be given by the polar coordinates r and θ : r the distance from the center of attraction, and θ the angular position. If the components of the rocket thrust per unit mass of the vehicle are R in the radial direction and Θ in the circumferential direction, and if g is the magnitude of gravitational attraction at the starting satellite orbit $r = r_0$ (Fig. 1), then the equations of motion of the space ship are

$$\frac{d^2 r}{dt^2} = R + r \left(\frac{d\theta}{dt} \right)^2 - g \left(\frac{r_0}{r} \right)^2 \quad (1)$$

and

$$\frac{d}{dt} \left(r^2 \frac{d\theta}{dt} \right) = r \Theta \quad (2)$$

By using the subscript 0 to indicate quantities at the starting instant $t = 0$, the equilibrium condition of the satellite orbit is given by

$$r_0 \left(\frac{d\theta}{dt} \right)_0^2 = g \quad (3)$$

Initially, the radial velocity is zero, i. e.,

$$\left(\frac{dr}{dt} \right)_0 = 0 \quad (4)$$

These are the initial conditions. For the space ship to have sufficient energy to escape the earth's gravitational field at the end of the powered flight, the sum of the kinetic energy and potential energy must vanish at the end of the

end of the accelerating period. Let that instant be denoted by the subscript 1.

Thus at $t = t_1$

$$\frac{1}{2} \left[\left(\frac{dr}{dt} \right)_1^2 + \left(r \frac{d\theta}{dt} \right)_1^2 \right] - g \frac{r_1^2}{r_1} = 0 \quad (5)$$

With any specified variation of the thrust forces R and Θ as functions of time, the above system of equations determine completely the take-off trajectory of the space ship. In the following sections, two special cases of practical significance will be discussed in detail: the case $R = \text{constant}$, $\Theta = 0$, purely radial thrust; and the case $R = 0$, $\Theta = \text{constant}$, purely circumferential thrust.

Radial Thrust

If the thrust is always radial and is proportional to the instantaneous mass of the vehicle, a non-dimensional thrust factor μ can be introduced as

$$R = \mu g \quad (6)$$

Furthermore, let

$$\tau = \frac{t}{t_1} \quad \eta = \frac{r}{r_1} \quad (7)$$

Then Eqs. (1) and (2) can be written in the non-dimensional form as

$$\frac{d^2 \eta}{d\tau^2} = \mu + \eta \left(\frac{d\eta}{d\tau} \right)^2 - \frac{1}{\eta^2} \quad (8)$$

and

$$\frac{d}{d\tau} \left(\eta^2 \frac{d\eta}{d\tau} \right) = 0 \quad (9)$$

Eq. (8) can be immediately integrated and by using the initial condition of Eq. (3), the result of integration is

$$\frac{d\eta}{d\tau} = \frac{1}{\eta^2} \quad (10)$$

By substituting this equation into Eq. (7), the final equation for ξ is

$$\frac{d\xi}{dt}^2 = \mu + \frac{1}{\xi^3} - \frac{1}{\xi^2} \quad (13)$$

The non-dimensional radial velocity is $d\xi/dt$. This is related to the physical radial velocity dr/dt as follows

$$\frac{dr}{dt} = \sqrt{gr_0} \frac{d\xi}{dt} \quad (14)$$

Eq. (10) can be rewritten as

$$\frac{1}{\xi} \frac{d}{dt} \left(\frac{d\xi}{dt} \right)^2 = \mu + \frac{1}{\xi^3} - \frac{1}{\xi^2}$$

Since $d\xi/dt = 0$ when $t = 0$ and $\xi = 1$ according to Eq. (4), the result of integrating the above equation is

$$\left(\frac{d\xi}{dt} \right)^2 = 2\mu(\xi - 1) + \left(1 - \frac{1}{\xi^2} \right) - 2\left(1 - \frac{1}{\xi} \right) \quad (15)$$

Therefore the non-dimensional time τ can be calculated as a function of the radius ξ as follows

$$\tau = \int \frac{\xi d\xi}{\sqrt{2(\xi-1)(2\mu\xi^2 - \xi + 1)}} \quad (16)$$

With Eqs. (9) and (12), the end condition of Eq. (5) can be written as

$$\frac{dr}{dt} = \sqrt{gr_0} \frac{d\xi}{dt} = 0 \quad \text{at} \quad \xi = \xi_1$$

Or simply

$$\xi_1 = 1 + \frac{1}{2\mu} \quad (17)$$

Then the velocities at the end of acceleration period are

$$\frac{dr}{dt} = \sqrt{gr_0} \frac{d\xi}{dt} = \sqrt{gr_0} \left(\frac{d\xi}{dt} \right)_1 \quad (18)$$

and

$$\left(r \frac{d\xi}{dt} \right)_1 = \sqrt{gr_0} \frac{1}{1 + \frac{1}{2\mu}}$$

The time τ_1 for the powered flight can be obtained from Eq. (14) by setting the upper limit of integration to β_1 . Thus the result of this integration is*

$$\tau_1 = \frac{1}{\sqrt{g}} \left[\frac{1 - \beta_1^{2n+1}}{2n+1} + F \left(\frac{\pi}{2}, \frac{1}{\sqrt{1-\beta_1^2}} \right) + E \left(\frac{\pi}{2}, \frac{1}{\sqrt{1-\beta_1^2}} \right) \right] \quad (15)$$

where F and E are the elliptical integrals of first kind and second kind respectively.

If $M(t)$ is the instantaneous mass of the space ship, and c the effective exhaust velocity of the rocket, then

$$RM = \mu g M = -c \frac{dM}{dt} = -c \sqrt{\frac{g}{c}} \frac{dM}{d\tau}$$

Therefore the mass ratio M_0/M_1 can be calculated as follows:

$$\ln(M_0/M_1) = \frac{\sqrt{g/c}}{c} \mu \tau_1$$

By using the result of Eq. (15),

$$\frac{c}{\sqrt{g}} \ln(M_0/M_1) = \frac{1 - \beta_1^{2n+1}}{2n+1} + \frac{\pi}{2} F \left(\frac{\pi}{2}, \frac{1}{\sqrt{1-\beta_1^2}} \right) + E \left(\frac{\pi}{2}, \frac{1}{\sqrt{1-\beta_1^2}} \right) \quad (16)$$

When the acceleration is very large, $\mu \gg 1$, the integrand in Eq. (14) can be expanded in terms of this parameter. Then the mass ratio is

$$\frac{c}{\sqrt{g}} \ln(M_0/M_1) = 1 + \frac{1}{24\mu^2} - \frac{1}{40\mu^4} + \dots \quad (17)$$

The relation of Eqs. (17) and (16) is plotted in Fig. 2. For $\mu = \frac{1}{8}$, the mass ratio becomes infinite. The reason is that at this value of

* The author is indebted to Dr. Y. T. Wu who kindly supplied the relation of Eq. (16).

Insert for p. 6

97'

Eq (175) shows that at very large values of the acceleration factor μ , the acceleration is accomplished in so short an interval that the circumferential velocity at the end of the acceleration remains at the initial value of $\sqrt{g r_0}$. The radial velocity increases from zero at the initial instant to the final value of $\sqrt{g r_0}$. The total kinetic energy is thus $g r_0$ at the end of acceleration and this is equal to the negative of potential energy at that instant, since the radial position r must be equal to the initial value r_0 at the end of the acceleration. The work of the rocket is to produce the radial velocity $\sqrt{g r_0}$. Thus it is evident that the value of $C \log(M_0/M_1)$ must be $\sqrt{g r_0}$, as the calculation shows.

acceleration, there is a radial position where the thrust force is equal to the gravitational attraction and ¹⁸one further increase in the energy of the vehicle can occur. Therefore the radial thrust per unit mass, if maintained constant throughout the powered flight, should be larger than $1/8$ g. With increasing thrust, the required mass ratio for escape from the earth's gravitational field decreases. The asymptotic value of $\frac{M}{M_0}$ is $1/8$. However there is no appreciable improvement in going to higher thrust than 1 g. This strong dependence of the mass ratio upon the acceleration factor is contrary to the opinion that for take off from earth the maximum velocity and thrust is required.

Circumferential Thrust

If the thrust is always circumferential and proportional to the mass of the vehicle, then a new thrust factor ψ can be introduced such that

$$\Theta = \psi g \quad (19)$$

By using the same non-dimensional variables as defined in Eq. (6), the equations of motion are

$$\frac{d^2 r}{dt^2} = -\frac{1}{r^2} + \psi \quad (20)$$

$$\frac{d^2 \theta}{dt^2} = 0 \quad (21)$$

The initial conditions of Eqs. (3) and (4) are

$$\left(\frac{dr}{dt}\right)_0 = 1, \quad \left(\frac{d\theta}{dt}\right)_0 = 0, \quad \psi = 1, \quad \tau = 0 \quad (22)$$

Therefore Eq. (20) gives another initial condition that

$$\left(\frac{d^2 r}{dt^2}\right)_0 = 0 \quad (23)$$

By eliminating β from Eqs. (20) and (21),

$$\frac{d}{dt} \left(\xi^3 \frac{d^2 \xi}{dt^2} + \xi \right)^{\frac{1}{2}} = \nu \xi \quad (24)$$

This is a third order differential equation with three initial conditions specified by Eqs. (22) and (23). No simple general solution can, however, be obtained. The following discussion is thus centered around approximations that are valid for large values of ν or small values of ν .

For very large values of ν , the acceleration period is expected to be short and the change of the radial position to be small. Then the value of ξ must be very close to the initial value of unity. By taking ξ to be unity, Eq. (24) becomes

$$\frac{d}{dt} \left(\frac{d^2 \xi}{dt^2} + 1 \right)^{\frac{1}{2}} = \nu$$

Then

$$\frac{d^2 \xi}{dt^2} + 1 = C^2 + 2C\nu t + \nu^2 t^2$$

where C is the integration constant. C , however, must be 1 because of the initial condition in Eq. (23). The appropriate approximate solution for ξ for very large ν is thus

$$\xi \approx 1 + \frac{1}{3} \nu t^3 + \frac{1}{12} \nu^2 t^4 \quad (25)$$

To obtain higher terms in this power series, the usual series substitution method may be used. The calculation is somewhat lengthy and therefore will not be reproduced here. The result is

$$\xi = 1 + \frac{1}{3} \nu t^3 + \frac{1}{12} \nu^2 t^4 - \frac{\nu}{60} t^5 - \frac{23\nu^2}{360} t^6 + \dots \quad (26)$$

By using the result of Eq. (26), the radial velocity is obtained by differentiation. Then Eq. (26) gives the circumferential velocity. The end condition of Eq. (5) can be modified into the following more convenient form by multiplying it by $2\tau^2$:

$$0 = \left[\left(\beta \frac{d\epsilon}{d\tau} \right)^2 + \left(\beta^2 \frac{d\beta}{d\tau} \right)^2 - 2\epsilon \right],$$

By substituting the solution of Eq. (26) into this condition, an equation for determining τ_1 is obtained.

$$1 - \frac{1}{2} \tau^2 + \frac{1}{2} \tau^4 + \frac{\gamma}{\tau} + \frac{1}{2} \tau^5 - \frac{\gamma^2}{\tau} / 4 - \epsilon = 0. \quad (27)$$

The mass ratio M_0/M_1 can be calculated in the same way as in the previous section and can be determined through the new parameter x defined as follows:

$$\frac{c}{\sqrt{g r_0}} \log(M_0/M_1) = \gamma \tau_1 = x \quad (28)$$

Eq. (27) then can be written as

$$1 - \frac{1}{2} x^2 + \frac{1}{2} x^4 + \frac{x}{\gamma} + \frac{1}{2} x^5 - \frac{\gamma}{4} = 0. \quad (29)$$

Since the calculation is designed for large values of γ , the appropriate expansion of x should be a series in inverse powers of γ . Eq. (29) suggests specifically

$$x/\gamma = x^{(0)} + \frac{x^{(1)}}{\gamma^2} + \frac{x^{(2)}}{\gamma^4} + \dots \quad (30)$$

L.C.

-9-

where $x^{(0)}$, $x^{(1)}$ and $x^{(2)}$ are constants independent of γ . By substituting Eq. (34) into Eq. (29) and equating equal powers of γ , the following set of equations results:

$$x^{(0)2} + 2x^{(0)} - 1 = 0 \quad (31)$$

$$x^{(1)} = \frac{1}{2(1+x^{(0)})} \left[\frac{2}{3} x^{(0)3} - x^{(0)4} - \frac{13}{15} x^{(0)5} - \frac{13}{90} x^{(0)6} \right] \quad (32)$$

$$\dots + \frac{1}{2} x^{(0)7} + \frac{1}{4} x^{(0)8} + \frac{1}{6} x^{(0)9} + \frac{1}{8} x^{(0)10} + \frac{1}{10} x^{(0)11} + \frac{1}{12} x^{(0)12} + \dots \quad (33)$$

The explicit numerical solutions are then

$$x^{(0)} = \sqrt{2} - 1 = 0.41421 \quad (34)$$

$$x^{(1)} = 0.002349$$

$$x^{(2)} = -0.00004791$$

This completes the calculation of mass ratio for large values of the acceleration factor γ .

For the other extreme case of very small values of γ , it is to be expected that in Eq. (24), the acceleration will be very small and the term $\frac{1}{2} \frac{d^2 \xi}{dt^2}$ will be very much smaller than ξ . Therefore a good approximation of Eq. (24) at small γ is

$$\xi = 1 \quad \text{or} \quad \frac{1}{2} \frac{d^2 \xi}{dt^2} = \gamma d\tau$$

The solution of this equation with the initial condition of $\xi = 1$ at $\tau = 0$ is

$$\xi = \frac{1}{1 - \gamma \tau^2} \quad (35)$$

Therefore

$$\frac{dr}{dt} = \frac{2\gamma}{(1-\gamma\tau)^3}, \quad \frac{d^2r}{dt^2} = \frac{6\gamma^2}{(1-\gamma\tau)^4} \quad \begin{matrix} 37 \\ (36) \end{matrix}$$

At $\tau=0$, the radial velocity and the radial acceleration are thus not zero as required by the initial conditions of Eqs. (22) and (24). They are however very small, because γ is very small. Therefore the solution of Eq. (35) is a good approximation to the exact solution.

To the same approximation, Eq. (20) becomes

$$r \frac{dl}{dt} = \frac{1}{r^{1/2}} = (1-\gamma\tau) \quad \begin{matrix} 38 \\ (37) \end{matrix}$$

This means that because of the extremely ^{small} acceleration, the centrifugal force per unit mass $\gamma \left(\frac{r}{dt} \right)^2$ practically balances the gravitational attraction at every instant. The end condition of Eq. (5) can then be written as

$$\frac{4\gamma^2}{(1-\chi)^6} - (1-\chi)^2 = 0 \quad \begin{matrix} 39 \\ (38) \end{matrix}$$

where χ is $\frac{V}{c}$. The appropriate solution for χ is then

$$\chi = 1 - (2\gamma)^{1/4} \quad \begin{matrix} 40 \\ (39) \end{matrix}$$

Since the mass ratio M_r/M_1 is related to χ by Eq. (28), Eq. (39) actually gives the mass ratio for escaping the gravitational field with very small acceleration.

The parameter χ is plotted against γ in Fig. 3, using both Eq. (38) with Eq. (34) and Eq. (39). When γ approaches zero, χ approaches 1.

Insert for § 11--

with practically no change in
the radial position.

¶ The acceleration factor γ is very large the rocket acts like an impulse. Since the thrust is in the circumferential direction, the rocket action only produces an increase in the circumferential velocity & the actual circumferential velocity is $\sqrt{2} \sqrt{g r_0}$ the required circumferential velocity for escape is $\sqrt{2} \sqrt{g r_0}$. Thus the increase of velocity produced by the rocket act is $(\sqrt{2}-1) \sqrt{g r_0}$. This explains the asymptotic value of x for very large γ .

hence the mass ratio M_0/M_1 , decrease monotonically. Therefore, same as the result for purely radial thrust, there is a strong influence of the magnitude of acceleration on the required mass ratio. However as far as decreasing the mass ratio is concerned, there is no appreciable advantage in using γ greater than 1/2.

Discussion

By comparing Fig. 2 with Fig. 3, it is apparent that the radial thrust is much less efficient than the circumferential thrust for take-off from the satellite orbit. For large thrusts, the value of $\log(M_0/M_1)$ for radial thrust is more than twice that for circumferential thrust. Furthermore, in case of radial thrust, the ratio of thrust to the instantaneous mass, if maintained such limit exist. Therefore circumferential thrust is definitely preferred.

The quantity $c \log(M_0/M_1)$ is a measure of the performance or the capability of the vehicle. It has the dimension of a velocity and is actually the increase of velocity which the vehicle is capable of in space without gravitation. This quantity is conveniently called the characteristic velocity of the vehicle. Let this be denoted by V . Then for the case of circumferential thrust, Eq. (28) gives

$$V = c \log(M_0/M_1) = \sqrt{g r_0} \lambda = \frac{\hat{v}}{\sqrt{2\lambda}} \lambda \quad (40)$$

where \hat{v} is the "escape velocity" from the surface of the earth and λ is the ratio of the radii of the satellite orbit and the earth. \hat{v} is equal to 11.2 km/sec. Fig. 3 then shows that by decreasing the acceleration k ,

1/2 to 1/3000 g. ρ , hence the required characteristic velocity V , will increase by a factor of two. This is a very important point for the designers of space ships.

$$\frac{1}{2} \frac{d}{dt} \left(\frac{1}{2} \frac{d}{dt} \right)$$

I have read your paper in Time of course. I find no reason to suspect my paper is not to seek a formal review, as I have seen the New York Office for just that purpose. The March-April issue of the Journal of the American Psychological Association is the best distribution.

Thank you for your evaluation of the Feldman paper. We are going ahead to publish it.

With best regards

Sincerely yours,

Martin Summerfield
Martin Summerfield

Section 7

Circumferential Acceleration

Incremental Acceleration

$$\frac{d}{dt}(r^2 \frac{d\theta}{dt}) = 0 \quad r$$

$$\frac{d^2 r}{dt^2} = r (\frac{d\theta}{dt})^2 - g \frac{r^2}{r^3}$$

$$(r^2 \frac{d^2 r}{dt^2} + g r_0^2 r) = r^2 \frac{d\theta}{dt}$$

$$\frac{d}{dt} (r^2 \frac{d^2 r}{dt^2} + g r_0^2 r) = 0$$

$$r = r_0 [1 + a_1 (\frac{t}{t_0})^2 + a_2 (\frac{t}{t_0})^3 + a_3 (\frac{t}{t_0})^4 + a_4 (\frac{t}{t_0})^5 + \dots]$$

$$\frac{d^2 r}{dt^2} = g [6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + 20 a_5 (\frac{t}{t_0})^4 + \dots]$$

$$r^2 = r_0^2 [1 + 3 a_3 (\frac{t}{t_0})^2 + \dots]$$

$$\frac{d^2 r}{dt^2} = g [6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + 20 a_5 (\frac{t}{t_0})^4 + \dots]$$

$$g r_0^2 r = g r_0^3 [1 + a_3 (\frac{t}{t_0})^2 + a_4 (\frac{t}{t_0})^3 + \dots]$$

$$r \frac{d^2 r}{dt^2} + g r_0^2 r = g r_0^3 [1 + 6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + (20 a_5 + a_3) (\frac{t}{t_0})^4 + 12 a_6 + \dots]$$

$$r \frac{d^2 r}{dt^2} + g r_0^2 r = g r_0^3 [1 + 6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + (20 a_5 + a_3) (\frac{t}{t_0})^4 + 12 a_6 + \dots]$$

$$= \frac{g}{t_0^2} [6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + (20 a_5 + a_3) (\frac{t}{t_0})^4 + 12 a_6 + \dots]$$

$$= \frac{g}{t_0^2} [6 a_3 (\frac{t}{t_0})^2 + 12 a_4 (\frac{t}{t_0})^3 + 27 a_5 (\frac{t}{t_0})^4 + 27 a_5 \cdot 6 a_4 (\frac{t}{t_0})^3 + \dots]$$

$$= \frac{g}{432} [27 a_5 (\frac{t}{t_0})^4 + 27 a_5 \cdot 6 a_4 (\frac{t}{t_0})^3 + \dots]$$

Let $\Theta = nq$

$$n \left[1 + \dots + a_3 \left(\frac{r}{r_0} \right)^{3/2} t^3 + \dots \right]$$

$$= 2a_3 + 2 \left[6a_4 - \frac{r}{2} t^2 \left(\frac{r}{r_0} \right)^{3/2} t + 3 \left[10a_5 + \frac{r}{2} - 18a_4 + \frac{r^2}{2} \left(\frac{r}{r_0} \right)^{3/2} t^2 \right. \right. \\ \left. \left. + \dots \right] \right] + \frac{r^2}{2} + 18a_4 + 9a_5 - 18a_4^2 - \frac{r}{2} a_3 (20a_4 + a_5) + 81a_4^2 a_5 - \frac{5r^2}{8} a_3 \left(\frac{r}{r_0} \right)^{3/2} t^2$$

then $n = 3a_3$,

$$6a_4 = \frac{r}{2} a_3^2$$

$$a_3 = \frac{r}{3}$$

$$a_4 = \frac{r^2}{12}$$

$$a_5 = -\frac{a_3}{20} + \frac{r}{10} a_3 a_4 - \frac{r}{20} a_3^2 = -\frac{r}{60} + r \left(\frac{r}{10} \cdot \frac{1}{3} \cdot \frac{1}{12} - \frac{r}{20} \cdot \frac{r}{27} \right)$$

$$a_5 = -\frac{r}{60}$$

$$\frac{r^2}{2} = \frac{a_3^2}{14} + r a_4 + \frac{r^2}{2} - \frac{r^2}{2} \left(\frac{r^2}{10} \right) - \frac{r}{2} \left(-\frac{r}{3} + \frac{r}{3} \right) + 9r^2 \frac{r^2}{12} = \frac{r^2}{8}$$

$$15a_6 = -\frac{23}{24} r^2$$

$$a_6 = -\frac{23r^2}{15 \cdot 24}$$

$$r = r_0 \left[1 + \frac{r}{3} t^2 + \frac{r^2}{12} t^4 - \frac{r}{60} t^5 - \frac{23r^2}{15 \cdot 24} t^6 + \dots \right], \quad t = \sqrt{\frac{r}{r_0}} t$$

$$\frac{d}{dt} = \frac{r}{r_0} \frac{d}{dt}$$

$$u = \frac{d}{dt} = \frac{r}{r_0} \left[r t^2 + \frac{r^2}{3} t^2 - \frac{r}{12} t^4 - \frac{23}{60} r^2 t^5, \dots \right]$$

$$u^2 = \frac{r}{r_0} \left[r^2 t^4 + \frac{2}{3} r^3 t^5 + \left(\frac{r^4}{9} - \frac{r^4}{6} \right) t^6 + \dots \right]$$

$$r^2 \left(\frac{db}{dt} \right) = r_0 \sqrt{\frac{a}{r_0}} + n r_0 \sqrt{\frac{a}{r_0}} \left[1 + \frac{n}{12} \tau^4 + \frac{n^2}{60} \tau^5 - \frac{n}{60} \tau^6 + \dots \right]$$

$$\left[r^2 \left(\frac{db}{dt} \right) = r_0 \sqrt{\frac{a}{r_0}} \left[1 + n\tau + \frac{n^2}{2} \tau^2 + \frac{n^3}{12} \tau^3 - \frac{n^2}{60} \tau^4 + \dots \right] \right]$$

$$\left(r^2 \frac{db}{dt} \right)^2 = r_0^3 \left[1 + 2n\tau + \frac{n^2}{2} \tau^2 + \frac{n^3}{12} \tau^3 + \frac{n^4}{60} \tau^4 + \frac{n^2}{60} \tau^5 + \frac{n^4}{60} \tau^6 + \frac{n^2}{60} \tau^7 + \frac{n^4}{60} \tau^8 + \dots \right]$$

$$= r_0^3 \left[1 + 2n\tau + \frac{n^2}{2} \tau^2 + \frac{n^3}{12} \tau^3 + \frac{n^4}{60} \tau^4 + \frac{n^2}{60} \tau^5 + \frac{n^4}{60} \tau^6 + \dots \right]$$

$$r u^2 = r_0^3 \left[1 + \frac{2}{3} n \tau + \frac{1}{6} n^2 \tau^2 + \frac{1}{12} n^3 \tau^3 + \frac{1}{60} n^4 \tau^4 + \dots \right]$$

$$= r_0^3 \left[n^2 \tau^2 + \frac{2}{3} n^3 \tau^3 - \frac{n^2}{6} (1 - \frac{2}{3} n^2) \tau^4 + \dots \right]$$

$$r^2 \left[u^2 + v^2 \right] = r_0^3 \left[1 + 2n\tau + \frac{n^2}{2} \tau^2 + \frac{1}{6} n^3 \tau^3 + \frac{1}{12} n^4 \tau^4 + \dots \right]$$

$$= 2 r_0^3 \left[1 + \frac{2}{3} n \tau + \frac{1}{6} n^2 \tau^2 + \frac{1}{12} n^3 \tau^3 + \frac{1}{60} n^4 \tau^4 + \dots \right]$$

r_0 is then given by

$$0 = -1 + 2n\tau_1 + n^2 \tau_1^2 - \frac{2}{3} n \tau_1^3 + n^2 \tau_1^4 + \frac{n}{30} (1 + 26n^2) \tau_1^5$$

$$+ \left\{ -\frac{2}{150} n^3 + \frac{13}{90} n^4 \right\} \tau_1^6 + \dots$$

4

$$nT_1 = x$$

$$= 2x + x^2 - \frac{2}{3} \frac{x^3}{n^2} + \frac{x^4}{n^2} + \frac{x^5}{n^2} + \frac{13}{15} \frac{x^5}{n^2} - \frac{8}{15} \frac{x^6}{n^2} + \frac{13}{90} \frac{x^6}{n^2} - \dots$$

$$x = x^{(0)} + \frac{x}{n^2} x^{(0)} + \frac{1}{n^2} x^{(0)} + \dots$$

$$x^2 = x^{(0)2} + \frac{2}{n^2} x^{(0)} x^{(1)} + \frac{1}{n^2} (x^{(1)2} + 2x^{(0)} x^{(2)}) + \dots$$

$$x^3 = x^{(0)3} + \frac{3}{n^2} x^{(0)2} x^{(1)} + \dots$$

$$x^4 = x^{(0)4} + \frac{4}{n^2} x^{(0)3} x^{(1)} + \dots$$

$$x^5 = x^{(0)5} + \frac{5}{n^2} x^{(0)4} x^{(1)} + \dots$$

$$x^6 = x^{(0)6} + \frac{6}{n^2} x^{(0)5} x^{(1)} + \dots$$

$$= x^{(0)} + x^{(1)} + \frac{1}{n^2} \left(2x^{(0)} + x^{(1)2} + 2x^{(0)} x^{(1)} + x^{(1)3} + x^{(2)} + x^{(0)2} + \frac{1}{n^2} x^{(1)4} \right) + \frac{1}{n^2} \left(2x^{(1)2} + x^{(0)2} + 2x^{(0)} x^{(1)} - \frac{2}{3} 3x^{(0)2} x^{(1)} + 4x^{(0)3} x^{(1)} + \frac{1}{30} x^{(0)5} + \frac{11}{15} 5x^{(0)4} x^{(1)} - \frac{8}{40} x^{(0)6} + \frac{11}{90} 6x^{(0)5} x^{(1)} \right)$$

$$x^{(1)} = x^{(0)} + \frac{1}{n^2} x^{(0)2}$$

$$x^{(2)} = x^{(0)} + \frac{1}{n^2} x^{(0)2}$$

$$x^{(3)} = x^{(0)} + \frac{1}{n^2} x^{(0)2} = \frac{1}{n^2} x^{(0)2} nT_1$$

$$\frac{1}{n^2} \frac{M_0}{M_1} = \frac{1}{n^2} x$$

$$2(1+x^n)x^n = \frac{2}{3}x^{3n} - x^{2n} - \frac{13}{15}x^{n^5} - \frac{12}{90}x^{n^6}$$

$$\Theta = \eta f$$

2

$$\eta \left[1 + \dots \right] = 3a_3 + 2 \left(1a_4 - \frac{2}{2} a_3^2 \right) \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t + 3 \left[10a_5 + \frac{a_2}{2} - 18a_3a_4 + \frac{27}{2} a_3^3 \right] \left(\frac{f}{r_0} \right) t^2 +$$

$$3a_3 = \eta, \quad a_3 = \eta/3$$

$$a_4 = \frac{1}{12} a_3^2 = \frac{\eta^2}{12}$$

$$a_5 = -\frac{a_3}{20} + \frac{1}{5} a_3 a_4 - \frac{27}{20} a_3^3$$

$$= -\frac{\eta}{20} + \frac{1}{5} \frac{\eta^3}{6} - \frac{27}{20} \frac{\eta^3}{27} = -\frac{\eta}{20}$$

$$\frac{f}{r_0} - 1 = \frac{\eta}{3} \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t^3 + \frac{\eta^2}{12} \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^4 - \frac{\eta}{20} \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^5 +$$

$$u = \frac{d}{dt} = \sqrt{\frac{f}{r_0}} \left[\eta \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t^2 + \frac{\eta^2}{12} \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^3 - \frac{\eta}{20} \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^4 \right]$$

$$r_0 \frac{d}{dt} + r^2 \frac{d}{dt} = \eta \sqrt{\frac{f}{r_0}} \left[t + \frac{1}{4} a_3 \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t^4 + \frac{1}{12} a_4 \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^5 + \frac{1}{20} a_5 \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^6 \right]$$

$$r^2 \frac{d}{dt} = \sqrt{\frac{f}{r_0}} \left[1 + \eta \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t + \frac{\eta^2}{12} \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^2 + \frac{\eta^3}{20} \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^3 - \frac{\eta}{12} \left(\frac{f}{r_0} \right)^{\frac{7}{2}} t^4 \right]$$

$$r = \sqrt{\frac{f}{r_0}} \left[1 + \frac{\eta}{2} \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t + \frac{\eta^2}{12} \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^2 - \frac{\eta}{20} \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^3 \right]$$

$$r \frac{d}{dt} = \sqrt{\frac{f}{r_0}} \left[1 + \eta \left(\frac{f}{r_0} \right)^{\frac{1}{2}} t - \frac{\eta}{2} \left(\frac{f}{r_0} \right)^{\frac{3}{2}} t^2 + \frac{11\eta^2}{12} \left(\frac{f}{r_0} \right)^{\frac{5}{2}} t^3 \right]$$

2) Case $R=0$

$$\frac{d}{dt} \left(r^2 \frac{d\theta}{dt} \right) = 0$$

$$r^2 \frac{d\theta}{dt} = r_0^2 \left(\frac{d\theta}{dt} \right)_0 + \int_0^t 0 \, dt$$

$$\frac{d^2 r}{dt^2} = \frac{1}{r^3} \left\{ r_0^2 \left(\frac{d\theta}{dt} \right)_0 + \int_0^t 0 \, dt \right\}^2 - \frac{r_0^2}{r^2}$$

Put $r_0 \left(\frac{d\theta}{dt} \right)_0^2 = f$,

$$\frac{d^2 r}{dt^2} = \frac{f}{r^3} - \frac{r_0^2}{r^2} \quad , \quad f = \frac{r_0^2}{r^2} \left(\frac{d\theta}{dt} \right)_0^2 = \frac{r_0^2}{r^2} \left(\frac{d\theta}{dt} \right)_0^2$$

So $\frac{d^2 r}{dt^2} = 0$ at $t=0$, $r=r_0$

Thus $(r-r_0) \sim t^3$
 $\frac{dr}{dt} \sim t^2 \sim (r-r_0)^{2/3}$

$$\begin{aligned} \text{Let } \int_0^t 0 \, dt &= nq \frac{1}{\sqrt{f} r_0} \int_{r_0}^r \frac{r \, dr}{\left(\frac{r}{r_0} - 1 \right)^{2/3}} \\ &= n \sqrt{\frac{f}{r_0}} r_0^2 \int_1^{r/r_0} \frac{\gamma \, d\gamma}{(\gamma-1)^{2/3}} \\ &= n \sqrt{\frac{f}{r_0}} r_0^2 \left[\frac{3}{4} (\gamma-1)^{1/3} + 3 (\gamma-1)^{4/3} \right]_{1}^{r/r_0} \\ &= n \sqrt{\frac{f}{r_0}} r_0^2 \left[\frac{3}{4} \left(\frac{r}{r_0} - 1 \right)^{1/3} + 3 \left(\frac{r}{r_0} - 1 \right)^{4/3} \right] \end{aligned}$$

$$\frac{dr}{dt} = n \sqrt{\frac{f}{r_0}} r_0^2 \left[\frac{3}{4} \left(\frac{r}{r_0} - 1 \right)^{1/3} + 3 \left(\frac{r}{r_0} - 1 \right)^{4/3} \right]$$
